ABSTRACT

In some implementations a non-transitory storage device on a smartphone having a multi-sensory-recognition engine stored thereon is coupled to a microcontroller, a device-controller for an electrical device that is wirelessly coupled to the microcontroller, and at least one of a plurality of sensors is operably coupled to the microcontroller.

SMARTPHONE CONTROL OF ELECTRICAL DEVICES

RELATED APPLICATIONS

This application is a continuation-in-part of, and claims the benefit under 35 U.S.C. 120 of U.S. Original application Ser. No. 13/931,820 filed on 29 Jun. 2013, which is a continuation of, and claims the benefit under 35 U.S.C. 120 of U.S. Original application Ser. No. 13/655,358 filed on 18 Oct. 2012, which is a continuation of, and claims the benefit under 35 U.S.C. 120 of U.S. Original application Ser. No. 12/698,133 filed on 30 Jan. 2009, which claims the benefit under 35 U.S.C. 119(e) of both U.S. Provisional Application Ser. No. 61/164,955 filed on 31 Mar. 2009 and U.S. Provisional Application Ser. No. 61/148,394 filed 1 Jan. 2009.

FIELD OF INVENTION

This disclosure relates to control of electrical devices.

DESCRIPTION OF RELATED ART

As the aging population and workers with disabilities increase, there are very few electrical device(s) available to assist them and those electrical device(s) are limited. Conventional control of the electrical devices has been very limited. The conventional control devices of the electrical devices include tactile control devices that include buttons to direct movement of the lifting device. The tactile control devices require a certain amount of physical dexterity that a particular patient may or may not have. At best, the tactile control devices as currently configured are inconvenient to use for some patients, and under the worse situations, the tactile control devices are impossible to use for other patients.

BRIEF DESCRIPTION

The above-mentioned shortcomings, disadvantages and problems are addressed herein, which will be understood by reading and studying the following specification.

In one aspect, a wireless mobile device controls at least one controllable electrical device from audio speech, by receiving the audio speech that is associated with the at least one controllable electrical device at a microphone of the wireless mobile device, generating speech data that is associated with a vocabulary set of the at least one controllable electrical device from the audio speech, converting the speech data to an ASCII string that is associated with the at least one controllable electrical device at the wireless mobile device, the ASCII string representing control data of the at least one controllable electrical device that is indicated by the audio speech, establishing a WIFI communication path with a WIFI wireless router that is associated with the at least one controllable electrical device at the wireless mobile device; and sending the ASCII string from the wireless mobile device to the WIFI wireless router that is associated with the at least one controllable electrical device through the WIFI communication path.

Apparatus, systems, and methods of varying scope are described herein. In addition to the aspects and advantages described in this summary, further aspects and advantages will become apparent by reference to the drawings and by reading the detailed description that follows.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of an overview of a system to control one or more electrical devices, according to an implementation;

2

FIG. 2 is a block diagram of apparatus to control one or more electrical devices in reference to patient healthcare condition, according to an implementation;

FIG. 3 is a block diagram of a plurality of electrical devices that can be controlled by a device controller;

FIG. 4 is a block diagram of a command interface unit apparatus that according to an implementation receives information from a human and generates command(s) from the human information, in reference to authority of the human and the state of the mind of the human;

FIG. 5 is a block diagram of a command interface unit apparatus that according to an implementation receives information from a human and generates command(s) from the human information, in reference to authority of the human and the state of the mind of the human;

FIG. 6 is a block diagram of a plurality of input devices that receive information in any one of a number of different communication methods, according to an implementation;

FIG. 7 is a diagram of a timeline to control a patient-lifting-device, according to an implementation involving trigger override command set words.

FIG. 8 is a block diagram of a voice data receiver that receives audio information, according to an implementation;

FIG. 9 is a block diagram of a patient-lifting-device controller that receives instructions and generates electrical signals that control a patient-lifting-device, according to an implementation;

FIG. 10 is a block diagram of a voice-recognition unit that receives audio information and generates commands that control a patient-lifting-device, according to an implementation;

FIG. 11 is a block diagram of a machine to heuristically adapt to sensory input, according to an implementation;

FIG. 12 is a block diagram of a hierarchical system of machines, according to an implementation;

FIG. 13 is a block diagram of a mobile device control system, according to an implementation;

FIG. 14 is a block diagram of a voice recognition enabled universal wireless remote control, according to an implementation;

FIG. 15 is a block diagram of an apparatus, according to an implementation.

FIG. 16 is a block diagram of a voice-recognition engine, according to an implementation;

FIG. 17 is a flowchart of a method to control a patient-lifting-device, according to an implementation;

FIG. 18 is a flowchart of a method to control a patient-lifting-device, according to an implementation;

FIG. 19 is a flowchart of a method to control a patient-lifting-device, according to an implementation involving trigger words;

FIG. 20 is a flowchart of a method to control a patient-lifting-device, according to an implementation involving trigger override command set words;

FIG. 21 is a flowchart of a method to control a patient-lifting-device, according to an implementation involving trigger words;

FIG. 22 is a flowchart of a method to update a database of authorities of a patient-lifting-device, according to an implementation;

FIG. 23 is a flowchart of a method to control a device-controller of a patient-lifting-device, according to an implementation;

FIG. 23 is a flowchart of a method to control a device-controller of a patient-lifting-device, according to an implementation;

3

FIG. 24 is a flowchart of a method to control a device-controller of a patient-lifting-device, according to an implementation;

FIG. 25 is a flowchart of a method to control a device-controller of a patient-lifting-device, according to an implementation;

FIG. 26 is a flowchart of a method to control a device-controller of a patient-lifting-device, according to an implementation;

FIG. 27 is a flowchart of a method to control a device-controller of a patient-lifting-device, according to an implementation;

FIG. 28 is a flowchart of a method to control a device having a safety stop, according to an implementation;

FIG. 29 is a flowchart of a method of customizing systems in FIG. 1 and FIG. 2, according to an implementation;

FIG. 30 is flowchart of a process of a voice and manual controlled switch, such as switch 3600 in FIG. 36, according to an implementation;

FIG. 31 is a flowchart of a method of a wireless mobile device controlling one or more controllable electrical devices that have an infrared control interface, according to an embodiment;

FIG. 32 is a flowchart of a method of a wireless mobile device controlling an electrical device that has an infrared control interface, according to an embodiment;

FIG. 33 is a block diagram of a voice-recognition unit for a patient-lifting-apparatus, according to an implementation;

FIG. 34 is an electrical schematic diagram of a voice-recognition apparatus to control a patient-lifting-apparatus, according to an implementation;

FIG. 35 is a block diagram of a device-controller of a patient-lifting-device, according to an implementation using DPTD relays;

FIG. 36 is an electrical schematic diagram of a voice and manual controlled switch, according to an implementation;

FIG. 37 is a mechanical diagram of a voice and manual controlled switch, according to an implementation;

FIG. 38 is an electrical schematic diagram of a voice controlled wall plug with manual invoice controlled circuitry, according to an implementation;

FIG. 39 is a mechanical diagram of a voice controlled wall plug with manual invoice controlled circuitry, according to an implementation;

FIG. 40 is an electrical schematic diagram of a voice and manual controlled light switch with manual and invoice controlled dimmer circuitry, according to an implementation;

FIG. 41 is a mechanical diagram of a voice and manual controlled light switch with manual and invoice controlled dimmer circuitry, according to an implementation;

FIG. 42 is an electrical schematic diagram of a voice controlled wall plug with manual and voice controlled dimmer circuitry, according to an implementation;

FIG. 43 is a mechanical diagram of a voice controlled wall plug with manual and voice controlled dimmer circuitry, according to an implementation;

FIG. 44 is a block diagram of a two dimensional patient-lifting-device, according to an implementation that is specifically adapted for lifting a patient out of bed;

FIG. 45 is a block diagram of a one dimensional patient-lifting-device, according to an implementation that is specifically adapted for lifting a patient in and out of a pool;

FIG. 46 is a block diagram of a mobile device, according to an implementation;

FIG. 47 is a block diagram of a communication subsystem component of the mobile device of FIG. 46, according to an implementation;

4

FIG. 48 is a block diagram of a system that is operable to control one or more controllable infrared electrical devices from audio speech, the system operable to control the at least one controllable infrared device through a wireless communication path, according to an implementation;

FIG. 49 is a block diagram of a system that is operable to control one or more controllable RF electrical devices from audio speech, the system operable to control the at least one RF controllable device through a wireless communication path, according to an implementation;

FIG. 50 is a block diagram of a WIFI wireless router according to an implementation. The WIFI wireless router is one example of the WIFI wireless router in FIG. 48 and the WIFI wireless router in FIG. 49;

FIG. 51-56 are diagrams of handheld mobile device graphical user interfaces selected to control electrical devices, according to implementations;

FIG. 51 is a diagram of a handheld mobile device graphical user interface selected to control a patient bed electrical device;

FIG. 52 is a diagram of a handheld mobile device graphical user interface selected to control a digital video recorder electrical device that is located in a bedroom;

FIG. 53 is a diagram of a handheld mobile device graphical user interface selected to control an electrical devices located in a first bedroom;

FIG. 54 is a diagram of a handheld mobile device graphical user interface selected to control a security camera electrical device located at a front door;

FIG. 55 is a diagram of a handheld mobile device graphical user interface selected to control a digital video recorder electrical device; and

FIG. 56 is a diagram of a handheld mobile device graphical user interface selected to control a patient bed electrical device.

DETAILED DESCRIPTION

In the following detailed description, reference is made to the accompanying drawings that form a part hereof, and in which is shown by way of illustration specific implementations which may be practiced. These implementations are described in sufficient detail to enable those skilled in the art to practice the implementations, and it is to be understood that other implementations may be utilized and that logical, mechanical, electrical and other changes may be made without departing from the scope of the implementations. The following detailed description is, therefore, not to be taken in a limiting sense.

The detailed description is divided into five sections. In the first section, a system level overview is described. In the second section, apparatus of implementations are described. In the third section, implementations of methods are described. In the fourth section, a hardware and the operating environment in conjunction with which implementations may be practiced are described. Finally, in the fifth section, a conclusion of the detailed description is provided.

System Level Overview

A system level overview of the operation of an implementation is described in this section of the detailed description.

FIG. 1 is a block diagram of an overview of a system 100 to control one or more electrical devices, according to an implementation. System 100 provides a convenient means to control an electrical device, such as an electrically-controlled patient-lifting-device. System 100 gives greater access to

electrical devices and services that elderly and physically challenged people are otherwise incapable of controlling, thus increasing independence and quality of life.

System 100 includes a command interface unit 102 that receives information in any one of a number of different communication methods from a human and transmits audio command(s) 104 to a processor 106. Examples of commands 104 to a processor 106 to control a patient-lifting device include “lift up” “move up” “lower down” “move down” “move forward” “forward” “move backward” “reverse” “stop” “go to sleep” “sleep” “activate” and “help.” One implementation of a number of different interface apparatus for the command interface unit 102 are described in FIG. 4 and another implementation of a number of different interface apparatus for the command interface unit 102 are described in FIG. 5. In some implementations, the command(s) 104 are transmitted from the command interface unit 102 over a radio frequency, without wired or cable transmissions lines, to the processor 106.

The processor 106 in system 100 receives the command(s) 104 and generates one or more instruction(s) 108 that are specifically tailored for a device-controller 110 that accomplish the command(s) 104. In some implementations, the instruction(s) 108 are transmitted over a radio frequency, without wired or cable transmissions lines, to the device controller 110.

The device-controller 110 receives the instruction(s) 108 and directs a programmable circuit device (PCD) 111 to generate one or more electric signal(s) 112 that are specifically tailored for an electrical device 114 that accomplish the one or more instruction(s) 108. The PCD 111 transmits the electrical signal(s) 112 to the electrical device 114. In some implementations, the electrical signal(s) 112 are transmitted over a radio frequency, without wired or cable transmissions lines, to the electrical device 114. When the electrical device 114 (e.g. a patient-lifting-device) operates in accordance with the electrical signal(s) 112 from the PCD 111, the electrical device 114 performs the command(s) 104 from the command interface unit 102. Other examples of the electrical device 114 are shown in FIG. 3.

The programmable circuit device (PCD) 111 is a semiconductor chip that contains a library of thousands of electronic components and software that is operable to link the components in such a way that they form one or more circuits. The PCD 111 contains a hardware library, a large number of input devices, controlling circuits and logic circuits which are programmed to interface input and output controls. Because the PCD 111 allows the creation of tens of thousands of different circuit combinations, the PCD 111 is operable to control virtually any device or system. The PCD 111 integrates microprocessors, complex programmable logic devices (CPLD), circuitry and software tools that dynamically create physical circuits and related process logic.

System 100 provides to elderly and physically challenged people greater access and control over the products, appliances and services that allows the elderly and physically challenged people to live a more independence and self-sufficient life. Some implementations of system 100 include a family of device controller(s) 110 and systems that have a mass-market appeal and thereby can be incorporated into everyday products. In some implementations, the electrical device 114 products are controlled without modification by physically challenged people by using a specialized system 100 that is specifically adapted to their individual needs.

In the implementations where the instruction(s) 108 are transmitted over a wireless communication path, and the device controller 110 is located within an exterior housing of

the electrical device(s) 114 or the device controller 110 is located within close proximity (e.g. within a few feet) of the electrical device(s) 114, the electrical device(s) 114 are referred to as wireless-controllable-devices. In some implementations, the device controller 110 is integrated not only within the housing of the electrical device, but integrated as a physical fixture within the electrical device 114. The system benefit the general populace while decreasing healthcare costs and dramatically opening the doors of opportunity for elderly and physically challenged people.

One implementation of system 100 includes a family of extremely inexpensive wireless remotely controlled devices (WRCD), in which each WRCD includes a device controller 110 and an electrical device 114 having widespread market appeal in which manufacturers of the electrical device(s) 114 can incorporate the device controller 110 into everyday electrical device(s) 114 such as lamps, dishwashers and machinery. In some implementations, electrical device(s) 114 are controlled by standard remote controls, voice control and special controls for physically challenged people. In some implementations, system 100 includes programmable circuit devices (PCD), wherein each PCD includes thousands of electronic components and software that link the components to form tens of thousands of different circuit combinations. Using a PCD controller, the circuits are configured through software. Because PCD controllers are mass produced and used in many electrical device(s) 114 the cost will be significantly less.

In a healthcare environment, system 100 reduces the need in patients for caregivers, allowing the patient more independence. In addition, system 100 supports cooperative agreements with manufacturers to incorporate WRCD in their electrical device(s) 114. Furthermore, system 100 supports development of infrastructures with nursing homes, hospitals and caregivers to assist in caring for the elderly; and provides patients with increased mobility, freedom and independence allowing the patients to remain in their own homes and communities for as long as possible.

In some implementations, system 100 provides greater access and control of elderly and physically challenged people over household appliance electrical device(s) 114 and services that will allow the physically challenged people to live a more independent and self sufficient life. In some implementations, system 100 includes a designed chip and software system that is a complete stand alone computer. An implementation of system 100 as a voice recognition system is the size of a cell phone, is battery operated and is wireless. In some implementations, system 100 provides a powerful, inexpensive, simple yet sophisticated control system for the elderly and physically challenged people giving them more access, freedom and control. In some implementations, system 100 includes a family of controls and systems that can be incorporated into everyday electrical device(s) 114 by manufacturing companies. By offering extremely inexpensive remote controlled device controller 110, a manufacturer can incorporate the device controller 110 into a wide variety of electrical device(s) 114 such as ceiling fans, lamps, dishwashers, irons, automatic doors and production machinery that is operable to all be controlled remotely, by voice and by specialized controllers. Thus the system benefits the general populace while decreasing healthcare costs and dramatically opening the doors of opportunity for the elderly and physically challenged people.

In residential environments, system 100 reduces the need for caregivers to attend to home-bound patients because of the independence of the command interface unit 102 and the processor, which comprise a programmable voice control

device. The safety of the elderly at home presents a constant concern for their loved ones. The thought of a sudden fall or the inability to move around the home with ease presents a continuous concern. Implementations of system **100** that include voice recognition in the command interface unit **102**, the voice control recognition assists in daily tasks from dialing 911, in case of an accident, to transporting an individual from the home to a place of safety in the event of a fire. In some implementations of systems **100**, the processor **106** can record a path of movement that is stored and replayed for future use; which is invaluable to the installation of home care devices and home care equipment such as rail systems, a home care lift, a transfer lift, a floor lift, a portable lift or a portable ceiling lift which are utilized and easily operated after being trained by a professional to maximize home mobility advantages. The comfort and accessibility of simply turning on the lights before entering a room, creates a safety zone in the home of the elderly.

System **100** provides functions that make the daily tasks of everyday living easier. Once an elderly person understands the functionality of systems **100** and uses system **100**, the elderly person will regain their independence, self-esteem and peace of mind. Mobility in the home will increase and the elderly will be able to remain at home longer rather than move to an assisted living residence. Some implementations of systems **100** regulate thermostats, open garage doors and operate electric wheelchair lifts.

In a hospital or nursing home setting, the voice recognition implementation of system **100** proves to be not only economical but practical in purpose. For example, using only 24 programmed voice commands, the environment of a single hospital room unit can be controlled. With the ability to reposition the bed for comfort, guide the movement of patient lifts, turn on and off lights, utilize the television, radio and telephone or signal for a caregiver, these activities are only a voice command away and protect the hospital's employees from injuries while assisting the patient.

In some implementations, system **100** includes a motorized patient lift system that is positionally aware and is controlled to orient and move a patient to any three dimensional location within the system limits. In a first implementation of this system, a patient lift system incorporates a lift motor driving a belt for lifting a patient upwardly off a bed. The motor is mounted for movement along a transverse rail. The transverse bar is mounted for movement in a direction perpendicular to the movement of the motor along the transverse bar, and between two laterally extending bars. By moving the motor along the transverse bar and moving the transverse bar along the laterally extending bars, one may move the patient as desired within the confines of a frame of the system. A frame is defined by the two laterally extending bars which are fixed to two longitudinally extending end bars. Another feature of the system is the ability to record a path of movement that is stored and replayed for future use, which was mentioned earlier also as part of the safety feature on transporting a person to a safe zone in the event of a fire. The objective is for the system to communicate with other positionally aware components to facilitate a process such as an exchange of the patient to a positionally aware wheelchair. This chip and software is interchangeable to adapt to other manufacturer's lift electrical device(s) **114**. This chip and software is adapted by manufacturers of motorized wheelchairs such as Quantum Rehab, Quickie® Rhythm™ and BraunAbility. A control component will allow manufactures to create and control a variety of sensory inputs such as voice control, micro switch head controls, puff tube controls or the combination of those controls easily programmed by the end user or the caregiver

for the correct functionality. This device will allow a wide variety of sensory inputs in any combination of full and semi electric hospital beds. Four programmable voice commands is operable to reposition the electric beds for comfort and safety. The voice recognition system controls the entire environment of a single hospital room unit. With just twenty four (24) programmable voice controls, the voice recognition system has the ability to reposition the bed for comfort, guide the movement of patient lifts, turn on and off lights, the television, radio and use the telephone or signal for a caregiver, these activities are only a voice command away and will save time, manpower and reduce the risk of injury to employees and patients. Once again, the remote control device has the ability to assist patients with more mobility, providing them with a sense of heightened security, independence and control.

System **100** provides two significant technical effects. One technical effect is the ability to control the entirety of a physical environment of a physically challenged person through system **100** that in some implementations provides a portable, universal, wireless, control remote device, the voice recognition system. In some implementations, the processor **106** is the size of a cell phone. In some implementations, the processor can generate instruction(s) **108** for an immense variety of electrical devices from over 10,000 command(s) **104** and thus those implementations of system **100** have the capacity to control an immense variety of electrical device(s) **114**. In particular, system **100** provides to caregivers and professional healthcare staff an ability to control a hospital room unit, a nursing home room or a bedroom in an assisted living residence. Some of the electrical device(s) **114** in a healthcare environment include telephone; bed; power lift; lights; nurse signal; television; VCR, DVD, radio and medication dispenser. Another technical effect of system **100** is the ability to program the chip and software system of a set of standard switches that enables manufacturers and developers of the standard switches to build the command interface unit **102** and the processor **106** and the device controller **110** into conventional electrical device(s) **114**, thus the conventional electrical device(s) **114** are then accessible for physically challenged people and elderly people. An implementation of system **100** as a voice recognition system is a wireless, universal remote voice control system adaptable to any electrical device that is programmed.

While the system **100** is not limited to any particular command interface unit **102**, command(s) **104**, processor **106**, instruction(s) **108**, device-controller **110**, PCD **111**, electric signal(s) **112**, and electrical device **114**, for sake of clarity a simplified command interface unit **102**, command(s) **104**, processor **106**, instruction(s) **108**, device-controller **110**, PCD **111**, electric signal(s) **112**, and electrical device **114** are described.

Apparatus Implementations

In the previous section, a system level overview of the operation of an implementation was described. In this section, the particular apparatus of such an implementation are described by reference to a series of diagrams.

FIG. 2 is a block diagram of apparatus **200** to control a patient-lifting-device in reference to patient healthcare condition, according to an implementation. Apparatus **200** provides a convenient means to control an electrical device, such as an electrically-controlled patient-lifting-device, in reference to patient healthcare condition.

Apparatus **200** includes one or more sensor(s) **202** of patient condition. Examples of the sensor(s) **202** include heart

rate sensor temperature sensor and blood pressure sensor. In apparatus 200, patient healthcare sensor data 204 from the patient healthcare sensor(s) 202 are received by the processor 106. The instruction(s) 108 that are generated by the processor 106 from the command(s) 104 of the command interface unit 102 are generated in reference to the patient healthcare data 204. Thus apparatus 200 generates instruction(s) 108 that ultimately control the electrical device 114 in any manner that is less detrimental to the patient in consideration of the healthcare condition of the patient as indicated by the patient healthcare sensor data 204.

In some implementations of apparatus 200, the command interface unit 102 of apparatus 200 performs voice recognition and interfaces with neural sensors, the neural sensors 202. The neural sensors are operable to identify electric signals naturally produced by the brain and reveal discreet emotional states and conscious thoughts. Sensors 202 detect as head movement, head rotation, eye and eyelid movement, lip movement, hand movement, diaphragm movement, nose movement, tongue movement, muscle movement, heart and respiratory rate, body temperature and skin electrical conductivity. The PCD can be adapted operate patient-lifting-device by a wireless, universal, voice remote controllable program. In some implementations, the command interface unit 102 and the PCD 111 are adapted to the analog signal process of a particular electrical device 114 such as patient-lifting-device manufactured by Molift™ AS of Ole Deviks vei 44, 0668 Oslo, Norway. The interface unit 102 and the PCD 111 is interchangeable to adapt to other manufacturer's lift electrical device(s) 114, such as wheelchair lifts and paratransit conversions in public-use transportation for the disabled.

The apparatus 200 is so simple to use that a caregiver will be able to customize apparatus 200 to the physical and mental capabilities of a patient to control various electrical device(s) 114, regardless of whether the electrical device 114 is a motorized wheelchair, a ceiling lift, home medical equipment or a household appliance. For example, by programming voice commands to the command interface unit 102, an operator will be able to adjust a hospital bed position, call for a caregiver, and turn off and on the lights independently. The voice commands to adjust the position of a bed will save caregivers, nursing homes and hospital staff hundreds of man hours, thereby saving time and money not to mention the reduced risk of injury.

FIG. 3 is a block diagram of a plurality of electrical devices 300 that can be controlled by a device controller. Each of the electrical devices 300 in FIG. 3 are examples of the electrical device 114 in FIG. 1 and FIG. 2. Device controller 110 in FIG. 1 is one example of the device controller.

One example of an electrical device that is controlled by a device controller is a computer 302. Another example of an electrical device that is controlled by a device controller is a cell phone or smartphone 304. A further example of an electrical device that is controlled by device controller is a light 306 or other illumination device. Yet another example of an electrical device is controlled by a device controller is a nurse call device 308. Still yet another example of an electrical device that is controlled by a device controller is an electrically controlled bed 310. Still yet a further example of an electrical device that is controlled by a device controller is a medical therapeutic device 312 such as an intravenous fusion device. One more example of an electrical device that is controlled by a device controller is an environmental control 314 such as a heating air-conditioning unit. An additional example of an electrical device that is controlled by a device controller is a patient-lifting-device 316. A different example of an electrical device that is controlled by a device controller

is a television 318. Yet one more example of an electrical device that is controlled by a device controller is a door 320 that includes actuation apparatus to open and close and lock and unlock the door 320. Still an additional example of an electrical device that is controlled by a device controller is a window covering 322 such as shades or blinds that include actuation apparatus to open and close the window covering 322.

FIG. 4 is a block diagram of a command interface unit apparatus 400 that according to an implementation receives information from a human and generates command(s) 104 from the human information, in reference to authority of the human and the state of the mind of the human. Apparatus 400 provides command(s) 104 that are suitable to be processed by a processor in control of a patient-lifting-device that are generated in reference to the authority in the state of mind of the human. Apparatus 400 is one implementation of the command interface unit 102 and FIG. 1 and FIG. 2.

The command interface unit 102 shown in FIG. 4 includes an input device 402 that receives information in any one of a number of different communication methods. One implementation of a number of different input devices 402 is described in FIG. 6. The received information is processed in a three-pronged approach. In a first prong, the information is processed by a command interpreter 408. The command interpreter analyzes the information and extracts a command 410 from the information. Examples of commands 410 include "lift up" "move up" "lower down" "move down" "move forward" "forward" "move backward" "reverse" "stop" "goto sleep" "sleep" "activate" and "help." In a second prong, the information is processed by a state-of-mind filter 412. The state-of-mind filter 412 analyzes the information and extracts from the information indicators of the emotional state of the operator, indicators of the competency of the operator, and/or indicators of the state-of-mind of the operator 414. In a third prong, the information is processed by an authority filter 416. The authority filter 416 analyzes the information and extracts from the information an indicator 418 of the authority of the operator. The identification of an individual by the authority filter 416 can be done through biometric identification such as voice identification, fingerprint identification or through external means such as a identification badge.

An authority engine 420 receives the command 410, the state-of-mind 414 and the indicator of authority of the operator 418. The authority engine 420 analyzes the command 410, the state-of-mind 414 and the indicator of authority of the operator 418 in reference to an authority database 422. In one implementation the authority engine 420 determines whether or not the command 410 is authorized by the authority of the operator 418. If the command 410 is not authorized by the authority of the operator 418, the command 410 is rejected. In another implementation the authority engine 420 determines whether or not the state-of-mind 414 of the operator is of a sufficient level for the command 410. If the state-of-mind 414 for the operator is not of a sufficient level for the command 410, the command 410 is rejected. If the command 410 is rejected (e.g. if the authority of the operator 518 is insufficient or the state-of-mind 414 of the operator is insufficient) a rejection process is initiated. In one implementation, the rejection process includes notifying a nurse of the rejection. In some implementations, no notice of the nurse is provided until the number of rejections equals or exceeds a threshold number of rejections w/in a predetermined amount of time.

If the authority engine 420 determines that both the state-of-mind 414 and the authority 418 of the operator are suffi-

11

cient for the command **410**, the authority engine **420** generates or designates an authorized command **424** from the command **410**.

FIG. **5** is a block diagram of a command interface unit apparatus **500** that according to an implementation receives information from a human and generates command(s) **104** from the human information, in reference to authority of the human and the state of the mind of the human. Apparatus **500** provides command(s) **104** that are suitable to be processed by a processor in control of a patient-lifting-device that are generated in reference to the authority in the state of mind of the human. Apparatus **500** is one implementation of the command interface unit **102** and FIG. **1** and FIG. **2**.

The command interface unit **102** shown in FIG. **5** includes an input device **502** that receives information in any one of a number of different communication methods. One implementation of a number of different input devices **502** is described in FIG. **6**. The received information is processed in a two-pronged approach. In a first prong, the information is processed by an authority filter **416**. The authority filter **416** analyzes the information and extracts from the information an indicator **418** of the authority of the operator. Thereafter, the information is processed by a command interpreter **502**. The command interpreter analyzes the information and extracts a command **410** from the information. Examples of commands **410** include "lift up" "move up" "lower down" "move down" "move forward" "forward" "move backward" "reverse" "stop" "goto sleep" "sleep" "activate" and "help." In a second prong, the information is processed by a state-of-mind filter **412**. The state-of-mind filter **412** analyzes the information and extracts from the information indicators of the emotional state of the operator, indicators of the competency of the operator, and/or indicators of the state-of-mind of the operator **414**.

An authority engine **412** receives the command **410**, the state-of-mind **414** and the indicator of authority of the operator **418**. The authority engine **420** analyzes the command **410**, the state-of-mind **414** and the indicator of authority of the operator **418** in reference to an authority database **422**. In one implementation the authority engine determines whether or not the command **410** is authorized by the authority of the operator **418**. If the command **410** is not authorized by the authority of the operator **418**, the command **410** is rejected. In another implementation the authority engine **420** determines whether or not the state-of-mind **414** of the operator is of a sufficient level for the command **410**. If the authority for the operator is not of a sufficient level for the command **410**, command **410** is rejected. If the authority for the operator is of a sufficient level for the command **410**, command **410** is accepted.

FIG. **6** is a block diagram of a plurality of input devices **600** that receive information in any one of a number of different communication methods, according to an implementation. Input devices **600** are implementations of the input devices **402** and FIG. **4** and FIG. **5**.

Input devices **402** include a conventional keyboard data receiver **602**, commonly known as a keyboard. In some implementations the keyboard includes alphanumeric keys for entering alphanumeric data. Input devices **402** also include an audio data receiver **604**. Input devices also include a synaptic data receiver **606**. The receivers **602**, **604** and **606** can be implemented either with a wireless connection to the command interface unit **102** and/or with a wired connection to the command interface unit **102**. The receivers **602**, **604** and **606** capture information **618** from an operator that is processed by the command interface unit **102** in FIG. **1**, FIG. **2** and/or FIG. **4**.

12

Another example of an input device **402** is a pressure sensitive device (piezo electric device) **608** mounted on and/or in the top of a tooth, that detects/senses pressure and transmits the pressure reading via a wireless connection (e.g. a Bluetooth communication link, or Zigbee communication link) to a processor. The pressure reading/measurement and/or time duration of the pressure reading/measurement is interpreted as an indicator or command to an external device, such as an indicator of a speed and/or direction of a lift device. Specifications for the Bluetooth communication link are published by the Bluetooth Special Interest Group located at 500 108th Avenue NE, Suite 250, Bellevue, Wash. 98004 Phone Number: +1.425.691.3535. Specifications for the ZigBee communication link are published by the ZigBee Alliance located at 2400 Camino Ramon, Suite 375, San Ramon, Calif. 94583. Some implementations the wireless tooth device tooth also detects/senses audio vibrations and transmits representations of the audio vibrations via the wireless connection to the processor. The representations of the audio vibrations are interpreted as an indicator or command to an external device, such as an indicator of a speed, amplitude or throttle (variation of power output) and/or direction of a lift device. The audio vibrations include vibrations transmitted through the solid matter of the tooth and the jaw bone and/or audio vibrations transmitted through the air and the mouth surrounding the audio receiver. Various implementation of the device mounted on a tooth include audio microphone, temperature monitor, saliva acidity sensor, pulse monitor sensor, voice vibration sensor (to sense jawbone vibrations), and with bit control for throttling of the speed of the patient-lifting-apparatus.

Other examples of an input device **402** include a joystick **610**, a puffer tube **612**, an eye movement detector **614**, and an electro-dermal anxiety sensor **616**.

FIG. **7** is a diagram of a timeline **700** to control a patient-lifting-device, according to an implementation involving trigger override command set words. While audio is received after time-0 **702**, a determination is made as to whether or not the volume of the audio is above a threshold for at least a predetermined amount of time between time-1 **704** and time-2 **706**. The audio level being above the threshold for predetermined amount of time between time-1 **704** and time-2 **706** is interpreted to indicate a possible emergency situation which might be dangerous to operate the patient-lifting apparatus. One example of the threshold volume of audio in method **1500** is 90 dB, however other implementations of other threshold levels of audio volume are implemented. If the audio level is determined to be not above the threshold for the predetermined amount of time between time-1 **704** and time-2 **706**, audio is continued to be received. If the audio level is greater than the audio volume threshold for at least the predetermined amount of time between time-1 **704** and time-2 **706**, a safety procedure is performed. Examples of the safety procedure are stopping movement of the patient-lifting-device, reversing movement, and reversing a previous action. After performing the safety procedure, audio is received starting at time-0 **702**. In some implementations the amount of predetermined time and/or the threshold level of audio volume can be modified through a user configuration interface.

FIG. **8** is a block diagram of a voice data receiver **800** that receives audio information, according to an implementation. Voice data receiver **604** in FIG. **8** is one implementation of the voice data receiver **604** in FIG. **6**. The voice data receiver **604** in FIG. **8** includes a microphone **802** that is operably coupled to a voice-recognition unit **804**. In some implementations, the voice-recognition unit **804** includes a component (not shown)

13

that suppresses or filters background environmental noise. Voice-recognition apparatus **3300** in FIG. **33** shows an implementation of voice-recognition unit **804**. Voice-recognition apparatus **3400** in FIG. **34** shows an implementation of voice-recognition unit **804**.

In some implementations the microphone **802** is located in close proximity to the mouth of the speaker in order to obtain clear audio data from the speaker. For example in some further implementations, the microphone **802** is located on a Bluetooth enabled earpiece. In other implementations, the microphone **802** is mounted on the end of a stalk of a headset. In other implementations, the microphone is mounted on a lapel clip.

FIG. **9** is a block diagram of a patient-lifting-device controller **900** that receives instructions and generates electrical signals that control a patient-lifting-device, according to an implementation. Lift controller **900** is one example of system **100** in FIG. **1** and apparatus **200** in FIG. **2**. The patient-lifting-device controller **900** includes a user interface **902** for device configuration that is operable to display, receive and/or store device configuration information for a patient-lifting-device, such as lift **112** in FIG. **1** and FIG. **2**. The device configuration user interface **902** is operably coupled to a modifiable logic circuit **904** that is operable to control the lift.

In one implementation, the modifiable logic circuit **904** is a field-programmable gate-array (FPGA) circuit in reference to the device configuration. In the FPGA implementation, the FPGA circuit is operable to receive digital audio input, and extract a command (e.g. command **104** in FIG. **1**) that is relevant to a patient-lifting-device (e.g. electrical device **114** in FIG. **1**) and the patient-lifting-device controller **900** includes a transmitter that is operable to send the command to a patient-lifting-device-controller (e.g. **111** in FIG. **1**).

FIG. **10** is a block diagram of a voice-recognition unit **1000** that receives audio information and generates commands that control a patient-lifting-device, according to an implementation. Voice-recognition unit **1000** includes an input device **402** that receives information in any one of a number of different communication methods. Examples of communication methods include audio and/or synaptic communication.

Voice-recognition unit **1000** also includes a volume filter **1002** that performs action **1904** in FIG. **19** and/or action **2004** in FIG. **20** on the information received from the input device **402**.

The information received from the input device is processed by a command interpreter **408**. The command interpreter analyzes the information and extracts a command **410** from the information.

Some implementations of voice-recognition unit **1000** includes a command set filter **1004** that includes one or more filters of the command set. For example, in some implementations, the command set filter **1004** includes the authority filter **416** of FIG. **4**. Some implementations of the command set filter **1004** also include the state-of-mind filter **412** of FIG. **4**. The implementations of apparatus **100** that include the command set filter **1004** also include an authority engine **420** as described in FIG. **4**. The authority engine **420** generates an authorized command **424**.

FIG. **11** is a block diagram of a machine **1100** to heuristically adapt to sensory input, according to an implementation. In some implementations, machine **1100** includes an initializer **1102** of a value of an expected time duration of performance **1104** of a command-set **1106** by a device **1108**. The source of the expected time duration of performance **1104** can be a human from which the expected time duration of performance **1104** is entered manually or the source of the expected time duration of performance **1104** can be a file that is

14

accessed by the machine. In some implementations, the expected time duration **1104** is a value that is referenced or accessed over long periods of time, during which the machine **1100** can be expected to be shutdown and powered off at least one time, in which case the expected time duration of performance **1104** is stored in a nonvolatile storage medium that is operably coupled to or a part of the machine **1100** so that the expected time duration of performance **1104** is available after any instance of the machine **1100** being powered-off. For example, in some implementations, the machine **1100** is implemented as the voice-recognition apparatus **3300** in which the expected time duration of performance **1104** is stored in nonvolatile memory in the voice-recognition apparatus **3300**.

In some implementations, the command-set is generated based on a combination sequence of at least one stimuli signal from the multisensor **1112**, the stimuli signal being selected from a group of a unisensory stimuli signals and a multisensory stimuli signal.

Some implementations of machine **1100** also include a receiver **1110** of a representation of the command-set **1106**. The representation of the command-set **1106** is received from one of a plurality of operable sensors **1112**. In some implementations, the receiver **1110** receives a command-set **1106** from a plurality of human sensory devices (e.g. plurality of operable sensors **1112**) by reading a sequence of 1 or more sensory stimulus and reading a sequence of 1 or more multisensory stimulus. In some implementations, the receiver **1110** receives a command-set **1106** from a plurality of human sensory devices (e.g. plurality of operable sensors **1112**) by reading a sequence of 1 or more sensory action and reading a sequence of 1 or more multisensory action. In some implementations, the receiver **1110** receives a command-set **1106** from a plurality of human sensory devices (e.g. plurality of operable sensors **1112**) by reading a sequence of 1 or more sensory input and reading a sequence of 1 or more multisensory input.

Some implementations of the machine **1100** also include a controller **1114** that is operable to instruct the device **1108** to perform the command-set **1106** in response to receipt of the representation of the command-set **1106**.

Some implementations of the machine **1100** also include a real-time performance timer **1116** that records the duration of the actual performance time-**1118** by the device **1108** of the command-set **1106**.

Some implementations of the machine **1100** also include a real-time monitor **1116** that is operable to compare the expected time duration of performance **1104** of the command-set **1106** by the device **1108** to the actual time duration of performance **1118** of the command-set **1106** by the device **1108**.

Some implementations of the machine **1100** also include an updater **1122** that is operable to transform the expected time duration **1104** to a value that is closer to the actual time duration of performance **1118** of the command-set **1106** by the device in response to completion of the command-set **1106** by the device **1108**. In some implementations, the updater **1122** is operable to transform the expected time duration **1104** in reference to a frequency of the representation of the performance quality of the device **1108** and to update the expected time duration **1104** in reference to an expected frequency of the representation of the performance quality of the device **1108**. For example, if the frequency of the representation of the performance quality of the device **1108** is greater than the expected frequency of the representation of the performance quality of the device **1108**, the expected time

15

duration **1104** is updated by a value that is more heavily weighted towards the actual performance time duration **1118**.

Some implementations of the machine **1100** also include an alarm component **1124** that is operable to activate in response to receipt of a representation of feedback **1126** of the device **1108**. The feedback **1126** is received through one of the plurality of operable sensors **1112**. The feedback **1126** indicates that the device **1108** is in error after instruction to the device to perform the command-set **1106**. The representation of feedback **1126** is received before completion of expected time duration **1104** of performance of the command-set **1106** by the device **1108**.

In some implementations, the feedback **1126** is adjusted according for one or more factors. For example, in some implementations the feedback **1126** is adjusted heuristically in reference to evaluations received from a human (e.g. a “stop” command-set **1106** received from a human indicates the previous command-set **1106** was a mistake). For example, in some implementations the feedback **1126** is adjusted by weighting of the heuristic adjustment based on the expected frequency of particular forms of feedback **1126** and/or the length of time from the command-set **1106** to receipt of the feedback **1126** (e.g. actual duration of the command). For example, a particular command-set **1106** that is expected to be followed frequently or commonly by a “stop” command will be weighted lightly in regards to the heuristic score of feedback **1126**. In another example, receiving a “Stop” command-set **1106** as feedback **1126** during the expected execution/performance duration of the previous command-set **1106** is highly weighted as negative feedback, the more immediately that a “Stop” command-set **1106** is received as feedback **1126** after the expected execution/performance duration of the previous command-set **1106** is lightly-weighted (e.g. less than 20%) or zero-weighted as negative feedback. For example, if a command-set is weighted lower and the expected duration of the command-set is 8 seconds, if 4 seconds into the expected duration, a “Stop” command-set is received, that “stop” command-set is heavily.

In some implementations the representation of the feedback **1126** of the device **1108** that is received through one of the plurality of operable sensors **1112** that indicates that the device **1108** is in error includes a representation of performance quality of the device **1108** that is received from a human through one of the plurality of operable sensors **1112** that further indicates that the device **1108** is in error. In some implementations, the representation of performance quality of the device **1108** that is received from the human through one of the plurality of operable sensors **1112** indicates that the device is in error includes a stop command-set. For example, the stop command-set is a verbal enunciation of “stop” by a human that will cease movement of the device **1108**. In some implementations of the machine **1100**, the machine also includes a receiver from a human of the value of the expected time duration **1104** of performance of the command-set by the device **1108**; one example of the receiver being a conventional keyboard text entry facility and interface in the machine **1100**.

FIG. **12** is a block diagram of a hierarchical system **1200** of machines, according to an implementation. In some implementations of system **1200**, system **1200** includes at least one controllable device **1202** operable. In some implementation system **1200** includes more than one controllable device **1202**. At least one of the controllable devices **1202** is operable to transmit a list of public functions **1204**. The public functions **1204** are functions that can be performed by the controllable device **1204** and that are available to be controlled, invoked and/or monitored by another device other than the at

16

least one controllable device **1202**, such as controller **1206**. The controllable device **1202** also includes a list of public data attributes **1208** of the at least one controllable device **1202**. The public data attributes can include data items that are stored in the controllable device **1202** that are available to be accessed, referenced, retrieved and/or updated by another device other than the at least one controllable device **1202**, such as the controller **1206**. One example of controller **1206** is microcontroller, processor or microprocessor **3302** in FIG. **33**, such as a RSC 6502 microcontroller.

Some implementations of system **1200** also include the controller **1206**. The controller **1206** is operable to control the at least one controllable device **1202**. The controller **1206** can be operably coupled to the at least one controllable device **1202** through a communication link **1210**, such as a wireless communication path. Some implementations of the controller **1206** are operable to receive the list of public functions **1204** of the at least one controllable device **1202**. Some implementations of the controller **1206** are operable to receive the list of public data attributes **1208** of the at least one controllable device **1202**.

Some implementations of the controller include a list of public functions **1212**. The public functions **1212** are functions that can be performed by the controller **1206** and that are available to be controlled, invoked and/or monitored by another device other than the controller **1206**, such as device **1214**.

Some implementations of the public functions **1212** include aggregations of the public functions **1204** of one or more controllable devices **1202**. In some further implementations, the public functions **1212** are aggregated by receiving public functions **1204** of one or more controllable devices **1202** and adding the list of public functions **1204** of the controllable device **1202** to the list of public functions **1212** of the controller **1206**.

Some implementations of the controller **1206** also include a list of public data attributes **1216** of the controller **1206**. The public data attributes **1216** can include data items that are stored in the controller **1206** that are available to be accessed, referenced, retrieved and/or updated by another device other than the controller **1206**, such as the device **1214**.

Some implementations of the public data attributes **1216** include aggregations of the public data attributes **1208** of one or more controllable devices **1202**. In some further implementations, the public data attributes **1216** are aggregated by receiving public data attributes **1208** of one or more controllable devices **1202** and adding the list of public data attributes **1208** of the controllable device **1202** to the list of public data attributes **1216** of the controller **1206**.

In some implementations of the controller **1206**, the controller **1206** is operable to transmit to another device (e.g. device **1214**) other than the at least one controllable device, the internal list of public functions **1212** of the controller **1206** and the internal list of public data attributes **1216** of the controller **1206**.

In some implementations device **1214** is a controllable controller that performs substantially the same functions in regards to aggregating public functions and public data attributes from other machines in the system **1200** that are lower in the hierarchy of devices and controllers and the controllable controller **1214** also is capable of publishing public functions and public data attributes to machines in the system **1200** that are higher in hierarchy of machines in the system **1200**.

One implementation of system **1200** merely includes at least one controllable device **1202**, at least one controllable controller **1214** that is operable to control the at least one

17

controllable device **1202** and the system **1200** includes a controller **1206** that is operable to control the at least controllable controller **1214**.

FIG. **13** is a block diagram of a mobile device control system **1300**, according to an implementation. Some implementations of system **1300** include at least one controllable mobile device **1302**. Examples of controllable mobile devices **1302** are powered wheelchairs and patient-lifting devices. Each controllable mobile device **1302** includes a component **1304** to identify a location **1306** of the at least one controllable mobile device **1302**. Examples of the component **1304** include a global positioning system (GPS) receiver that is operable to receive GPS satellite signals from which a position of the controllable mobile device **1302** is triangulated.

Some implementations of mobile device control system **1300** include one or more multisensory control device(s) **1308**. Each multisensory control device **1308** includes at least one multisensory input apparatus **1310** that is operable to transform multisensory control instructions **1312** (from a human through a sensor e.g. microphone **1314**) to one or more control instruction(s).

Some implementations of the multisensory control device **1308** include a sensory input apparatus **1310** that is an electrodermal sensor **1320**. The electrodermal sensor **1320** senses electrical resistance in skin surface of a subject. The multisensory input apparatus **1310** interprets the electrodermal resistance as a measure of stress in the subject and the multisensory control device **1308** generates control instruction(s) in accordance with the measure of stress. In some implementations, the multisensory control device **1308** generates control instruction(s) **1316** to stop or halt movement or operation of the controllable mobile device **1302** the device when the interpreted measure of stress exceeds a threshold and multisensory control device **1308** generates control instruction(s) **1316** to activate or enable movement of the controllable mobile device **1302** when the interpreted measure of stress is less than a threshold.

Some implementations of mobile device control system **1300** include one or more controllable controller(s) **1318** that are operable to control the at least one controllable mobile device **1302** in reference to the location **1306** of the at least one controllable mobile device **1302** and the control instructions(s) **1316**.

FIG. **14** is a block diagram of a voice recognition enabled universal wireless remote control **1400**, according to an implementation. Bluetooth headset **1402** and Bluetooth transceiver **1404** facilitate verbal communications.

The user can send and receive verbal and audio communications either through the use of microphone **1406** and speaker **1410** or through the use of Bluetooth headset **1402** which communicates through Bluetooth transceiver **1404**. Audio circuit **1412** communicates the sound information to the voice recognition module **1414**. Voice recognition module **1414** monitors the input sound information with pattern recognition to identify trigger phrases. Once a trigger phrase is identified, the voice recognition module **1414** enters a command recognition mode for a pre-determined time, during which the voice recognition module **1414** monitors the input sound information with pattern recognition to identify commands. Once a command is recognized by the voice recognition module **1414**, the control logic **1424** routes an appropriate ActionSet to a Bluetooth Linking Management and Data Routing Module **1422**. If device control logic **1424** identifies the ActionSet being a Zigbee instruction set, the device control logic **1424** routes the predefined instruction set of the ActionSet to the Zigbee transceiver **1426** which in turn com-

18

municates the instruction set to Zigbee transceiver remote device **1428** which executes the appropriate action.

If device control logic **1424** identifies the ActionSet as being a Z-Wave instruction set, then the device control logic **1424** routes the predefined instructions set to the Z-Wave transceiver **1430** which in turn communicates the instructions set to Z-Wave transceiver remote device **1432** which executes the appropriate action.

If device control logic **1424** identifies the ActionSet being a Z-Wave instruction set, the device control logic **1424** routes the predefined instructions set to the Z-Wave transceiver **1428** which in turn communicates the instruction set to Z-Wave transceiver remote device **1430** which executes the appropriate action.

Some implementations of the Bluetooth Linking Management and Data Routing Module **1422** relates to radio transceiver devices for communicating voice and data using a predetermined protocol. Bluetooth transceivers such as Bluetooth distal transceiver are an example of such devices. Apparatus **1400** performs voice recognition to link and associate two or more devices in addition to routing voice and data communications.

In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** provides audio and visual notification of previously associated devices. In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** provides device audio and textual naming protocol. In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** provides device sensing and acquisition. In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** provides audio and visual notification of previously unassociated devices.

In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** incorporates one or more Bluetooth compatible transceivers and a voice controlled Bluetooth device that links devices and routes data.

In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** includes device connection specification that is a set of criteria and specifications that are use to manage the linking, data flow and interaction of Bluetooth devices. The device connection specification includes but is not limited to a device identity, a device audio name, a device text name, activity state, activity priority, interrupt threshold, start time and end time.

In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** provides linking and associations between Bluetooth devices through voice commands.

In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** provides different modes of notification, in which, the Bluetooth Linking Management and Data Routing Module **1422** is operable to track other Bluetooth devices available to the Bluetooth Linking Management and Data Routing Module **1422** and notify the user of any changes in status including but not limited to the introduction of a new device that is communicating in conformance to the Bluetooth protocol, the absence of a previously detected device, change in the signal strength of previously detected devices, activity on previously detected devices, request for linking, request for association.

A Bluetooth connection specification is a set of criteria and specifications that define linking, data flow and interaction of device that communicate in accordance to the Bluetooth protocol. The Bluetooth connection specification includes but is

not limited to a device identity, a device audio name, a device text name, activity state, activity priority, interrupt threshold, start time and end time.

In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** recognizes multiple variations and versions of the Bluetooth connection specification for any given Bluetooth device.

In some implementations, the Bluetooth Linking Management and Data Routing Module **1422** provides a facility for a user to access to create criteria sets for notification for individual devices and groups of devices. For example, a Bluetooth device named "headset" incorporates a voice controlled Bluetooth device that links to the Bluetooth Linking Management and Data Routing Module **1422** through a Bluetooth transceiver **1423**. In addition, the user can create a criteria set named "Cell phone one daytime home" for one or more remote Bluetooth devices, such as Bluetooth-capable device **1418** or Bluetooth-capable cell phone **1420**, each of which can include multiple remote voice command device activity states for each of which can have its own interrupt threshold, wherein the user can define device activity state's with specific interrupt threshold that can be associated with particular devices and activities. Activities can include notification of the introduction of the availability of one or more Bluetooth devices **1418** or **1420** by and audio notification of "cell phone two is available." Activities can also include notification of the absence of a previously detected Bluetooth device **1418** or **1420** by an audio notification of "cell phone two is no longer available." Activities can also include notification of a weak signal strength in the Bluetooth-capable cell phone **1420** by an audio notification of "cell phone one signal is weak."

If device control logic **1424** identifies the ActionSet as being an Infrared instruction set that the device control logic **1424** routes the predefined instructions set to the Infrared Emitter **1434** which in turn communicates the instructions set to Infrared Emitter remote device **1436** which executes the appropriate infrared action.

If device control logic **1424** identifies the ActionSet as being a Communications and Command Protocol instruction set that the device control logic **1424** routes the predefined instructions set to a Communications and Command Protocol transceiver **1438** which in turn communicates the instructions set to a Communications and Command Protocol remote device **1440** which executes the appropriate Communications and Command Protocol action.

FIG. 15 is a block diagram of an apparatus **1500**, according to an implementation. Apparatus **1500** includes a controller **1502**. The controller **1502** includes a wireless transceiver component **1504** and a software configurable circuit **1506** having multisensory recognition capability. In some implementations, the software configurable circuit **1506** further comprises a field-programmable gate array (FPGA).

Apparatus **1500** also includes a controllable device **1508** that includes a native control circuit **1510** and a large scale programmable circuit **1512** that is operable to receive signals **1514** from the controller **1502** and is operable to transform the signals **1514** from the controller into native control signals **1516** of the controllable device **1508**, and the large scale programmable circuit **1512** is operable to transmit the native control signals **1516** to the native control circuit **1510**. In some implementations, the large scale programmable circuit **1512** is a very-large-scale integrated (VLSI) circuit that includes power relays.

FIG. 16 is a block diagram of a voice-recognition engine **1600**, according to an implementation. The voice-recognition engine **1600** includes a frontend component **1602** parameterizes an input signal (e.g., audio) into a sequence of output

features **1604**. The frontend component **1602** includes one or more parallel chains of replaceable communicating signal processing modules called data-processors (not shown). Supporting multiple chains of data-processors of the front-end **1602** permits simultaneous computation of different types of parameters from the same or different input signals. The simultaneous computation enables simultaneous decoding using different parameter types, and even parameter types derived from non-speech signals such as video.

Each data-processor in the frontend component **1602** provides an input and an output that can be connected to another data-processor of the front-end **1602**, permitting arbitrarily long sequences of chains of data-processors. The inputs and outputs of each data-processor of the front-end **1602** are generic data objects that encapsulate processed input data as well as markers that indicate data classification events such as end-point detection. The last data-processor of the front-end **1602** in each chain produces a data object composed of parameterized signals (e.g. features **1604**) to be used by a decoder component **1606**.

The voice-recognition engine **1600** produces parallel sequences of features **1602**. The voice-recognition engine **1600** allows for an arbitrary number of parallel streams.

Communication between blocks follows a pull design. With a pull design, a data-processor of the front-end **1602** requests input from an earlier module only when needed, as opposed to the more conventional push design, where a module propagates its output to the succeeding module as soon as the output is generated. This pull design enables the processors to perform buffering, allowing consumers to look forwards or backwards in time.

The ability to look forwards or backwards in time not only permits the decoder component **1606** to perform frame-synchronous Viterbi searches, but also allows the decoder component **1606** to perform other types of searches such as depth-first and A*.

Within the generic frontend component **1602** framework, the voice-recognition engine **1600** provides a suite of data-processors of the front-end **1602** that implement conventional signal processing techniques. These implementations include support for the following: reading from a variety of input formats for batch mode operation, reading from the system audio input device for live mode operation, preemphasis, windowing with a raised cosine transform (e.g., Hamming and Hanning windows), discrete fourier transform (EFT), mel frequency filtering, bark frequency warping, discrete cosine transform (DCT), linear predictive encoding (LPC), end pointing, cepstral mean normalization (CMN), mel-cepstra frequency coefficient extraction (MFCC), and perceptual linear prediction coefficient extraction (PLP).

The voice-recognition engine **1600** includes a search-manager component **1608** generates active-lists **1610** from currently active tokens in the search trellis by pruning using a pluggable pruner component **1612**. A pruner component **1612** can perform relative and/or absolute beam pruning. The implementation of the pruner component **1612** is greatly simplified by the garbage collector of a Java platform. With garbage collection, the pruner component **1612** prunes a complete path by merely removing the terminal token of the path from the activelist **1610**. The act of removing the terminal token identifies the token and any unshared tokens for that path as unused, allowing the garbage collector to reclaim the associated memory.

The search-manager component **1608** sub-framework also includes a scorer component **1614**, a pluggable state probability estimation module that provides state output density values on demand. When the Search-manager component

1608 requests a score for a given state at a given time, the scorer component 1614 accesses the feature vector for that time and performs the mathematical operations to compute the score. In the case of parallel decoding using parallel acoustic models, the scorer component 1614 matches the acoustic model set to be used against the feature type.

The scorer component 1614 retains all information pertaining to the state output densities. Thus, the search-manager component 1608 need not store data indicating whether the scoring is done with continuous, semi-continuous or discrete hidden Markov models (HMMs). Furthermore, the probability density function of each HMM state is isolated in the same fashion. Any heuristic algorithms incorporated into the scoring procedure for speeding the scorer component 1614 can also be performed locally within the scorer component 1614. In addition, the scorer component 1614 can take advantage of multiple processors if they are available.

The voice-recognition engine 1600 includes a linguist component 1616 generates a search-graph 1618 that is used by the decoder component 1606 during the search, while at the same time hiding the complexities involved in generating a graph. The linguist component 1616 is a pluggable module, allowing people to dynamically configure the system with different linguist components 1616.

A typical linguist component 1616 constructs the search-graph 1618 using the language structure as represented by a given language-model 1620 and the topological structure of the acoustic-model 1624 (HMMs for the basic sound units used by the system). The linguist component 1616 may also use a dictionary 1622 (typically a pronunciation lexicon) to map words from the language-model 1620 into sequences of acoustic-model 1624 elements. When generating the search-graph 1618, the linguist component 1616 may also incorporate sub-word units with contexts of arbitrary length.

The graph is a directed graph in which each node, called a search state, represents either an emitting or a non-emitting state. Emitting states can be scored against incoming acoustic features while non-emitting states are generally used to represent higher-level linguistic constructs such as words and phonemes that are not directly scored against the incoming features 1602. The arcs between states represent the possible state transitions, each of which has a probability representing the likelihood of transitioning along the arc.

By allowing different implementations of the linguist component 1616 to be plugged in at runtime, the voice-recognition engine 1600 permits individuals to provide different configurations for different system and recognition requirements. For instance, a simple numerical digits recognition application might use a simple linguist component 1616 that keeps the search space entirely in memory. On the other hand, a dictation application with a 100K word vocabulary might use a sophisticated linguist component 1616 that keeps only a small portion of the potential search space in memory at a time.

The linguist component 1616 itself includes of three pluggable components: a language-model 1620, a dictionary 1622, and an acoustic-model 1624, which are described in the following sections.

The language-model 1620 module of the linguist component 1616 provides word-level language structure, which can be represented by any number of pluggable implementations. These implementations typically fall into one of two categories: graph-driven grammars and stochastic N-Gram models. The graph-driven grammar represents a directed word graph where each node represents a single word and each arc represents the probability of a word transition taking place. The

stochastic N-Gram models provide probabilities for words given the observation of the previous n-1 words.

The dictionary 1622 provides pronunciations for words found in the language-model 1620. The pronunciations break words into sequences of sub-word units found in the acoustic-model 1624. The dictionary 1622 interface also supports the classification of words and allows for a single word to be in multiple classes. The various implementations optimize for usage patterns based on the size of the active vocabulary. For example, one implementation will load the entire vocabulary at system initialization time, whereas another implementation will only obtain pronunciations on demand.

The acoustic-model 1624 module provides a mapping between a unit of speech and an HMM that can be scored against incoming features 1602 provided by the frontend component 1602. As with other systems, the mapping may also take contextual and word position information into account. For example, in the case of triphones, the context represents the single phonemes to the left and right of the given phoneme, and the word position represents whether the triphone is at the beginning, middle, or end of a word (or is a word itself). The contextual definition is not fixed by the voice-recognition engine 1600, allowing for the definition of the acoustic-model 1624 that contain allophones as well as the acoustic-model 1624 whose contexts do not need to be adjacent to the unit.

Typically, the linguist component 1616 breaks each word in the active vocabulary into a sequence of context-dependent sub-word units. The linguist component 1616 then passes the units and their contexts to the acoustic-model 1624, retrieving the HMM graphs associated with those units. The linguist component 1616 then uses these HMM graphs in conjunction with the language-model 1620 construct the search-graph 1618.

The HMM is a directed graph of objects. In this graph, each node corresponds to an HMM state and each arc represents the probability of transitioning from one state to another in the HMM. By representing the HMM as a directed graph of objects instead of a fixed structure, an implementation of the acoustic-model 1624 can easily supply HMMs with different topologies. For example, the acoustic-model 1624 interfaces do not restrict the HMMs in terms of the number of states, the number or transitions out of any state, or the direction of a transition (forward or backward). Furthermore, the voice-recognition engine 1600 allows the number of states in an HMM to vary from one unit to another in the same acoustic-model 1624.

Each HMM state is capable of producing a score from an observed feature. The actual code for computing the score is done by the HMM state itself, thus hiding its implementation from the rest of the system, even permitting differing probability density functions to be used per HMM state. The acoustic-model 1624 also allows sharing of various components at all levels. That is, the components that make up a particular HMM state such as Gaussian mixtures, transition matrices, and mixture weights can be shared by any of the HMM states to a very fine degree.

Individuals can configure the voice-recognition engine 1600 with different implementations of the acoustic-model 1624 based upon their needs. The voice-recognition engine 1600 provides a single acoustic-model 1624 implementation that is capable of loading and using acoustic models.

Even though the linguist component 1616 may be implemented in very different ways and the topologies of the search spaces generated by these, the linguist component 1616 can vary greatly, the search spaces are all represented as a search-

graph **1618**. The search-graph **1618** is the primary data structure used during the decoding process.

Method Implementations

In the previous section, apparatus of the operation of an implementation was described. In this section, the particular methods performed by a processor of such an implementation are described by reference to a series of flowcharts.

In some implementations, methods **1700-3000** are implemented as a sequence of instructions which, when executed by a processor, such as processor unit **4704** in FIG. **47**, microcontroller **3302** in FIG. **33** or processor **106** in FIG. **1** and FIG. **2**, cause the processor to perform the respective method. In other implementations, methods **1700-3000** are implemented as a computer-accessible or a computer-usable medium having executable instructions capable of directing a processor, such as microprocessor for in FIG. **14**, microcontroller **3302** in FIGS. **33** and **3402** in FIG. **34** or main processor **4602** in FIG. **46**, to perform the respective method. In varying implementations, the medium is a magnetic medium, an electronic medium, or an optical medium.

FIG. **17** is a flowchart of a method **1700** to control a patient-lifting-device, according to an implementation. Method **1700** receives information from a human and generates a command from the human information, in reference to authority of the human and the state of the mind of the human. Method **1700** generates command(s) that are suitable to be processed by a processor in control of a patient-lifting-device. In some implementations, method **1700** is performed by the command interface unit **102** and FIG. **1** and FIG. **2**.

Method **1700** includes receiving **1702** information from any one of a number of different communication devices. FIG. **6** describes some implementations of communication devices. Method **1700** includes processing the information by analyzing the information and extracting **1704** a command from the information. Examples of the command include "lift up" "move up" "lower down" "move down" "move forward" "forward" "move backward" "reverse" "stop" "goto sleep" "sleep" "activate" and "help." Method **1700** includes processing the information by analyzing and extracting **1706** from the information indicators of the emotional state of the operator, indicators of the competency of the operator, and/or indicators of the state-of-mind of the operator.

Method **1700** includes processing the information by analyzing the information and extracting **1708** from the information an indicator of the authority of the operator. In some implementations, extracting an indication of authority of the operator includes identifying the operator. For example, where the information **1702** is audio information from a human speaker, the identity of the human speaker is determined and the authority of that speaker is then determined. In some implementations, the speech pattern of the human speaker is compared to a database of known humans. The database is created prior to the performance of method **1700** from recorded speech sample recordings of humans who are authorized to enter the healthcare facility, such as healthcare providers, non-professional employees of the healthcare facility, patients, and friends, relatives and/or coworkers of the patient. Each human whose speech sample is recorded in the database is associated with a particular authority. An example of an authority is "full authority" in which the human is authorized to exercise or command all functions of the lift. Another example of an authority is "no authority in which the human is not authorized to exercise or command any function of the lift. In method **1700**, the database is accessed and a comparison of the information **1702** to the speech samples in

the database is performed. When the comparing determines the identity of the human speaker, the authority of the identified human is accessed and used as the indicator of authority of the operator.

In method **1700**, the command, the state-of-mind and the indicator of authority of the operator is analyzed **1710** to an authority database to determine whether or not the command is authorized by the authority of the operator in consideration of the emotional state of the operator. If the command is not authorized by the authority and emotional state of the operator, the command is rejected **1712**. In some implementations, rejecting **1712** the command can include transmitting a notice of an attempted unauthorized command to supervisory personnel or law enforcement agency. If the command is determined to be authorized, the command is transmitted **1714** to the processor (e.g. **106** in FIG. **1**) and the command **1712** is performed by the lift. In some implementations, a log or journal of all extracted commands in action **1704** and the determination **1710** of the authority of the extracted commands is stored.

Method **1800** includes receiving **1702** information from any one of a number of different communication devices. FIG. **6** describes some implementations of communication devices.

Method **1800** includes processing the information by analyzing the information and extracting **1708** from the information an indicator of the authority of the operator. In some implementations, extracting an indication of authority of the operator includes identifying the operator. For example, where the information **1702** is audio information from a human speaker, the identity of the human speaker is determined and the authority of that speaker is then determined. In some implementations, the speech pattern of the human speaker is compared to a database of known humans. In method **1800**, the database is accessed and a comparison of the information **1702** to the speech samples in the database is performed. When the comparing determines the identity of the human speaker, the authority of the identified human is accessed and used as the indicator of authority of the operator.

Method **1800** includes processing the information by analyzing the information and extracting **1802** a command from the information. Examples of the command include "lift up" "move up" "lower down" "move down" "move forward" "forward" "move backward" "reverse" "stop" "goto sleep" "sleep" "activate" and "help." Method **1800** includes processing the information by analyzing and extracting **1706** from the information indicators of the emotional state of the operator, indicators of the competency of the operator, and/or indicators of the state-of-mind of the operator.

In method **1800**, the command, the state-of-mind and the indicator of authority of the operator is analyzed **1710** to an authority database to determine whether or not the command is authorized by the authority of the operator in consideration of the emotional state of the operator. If the command is not authorized by the authority and emotional state of the operator, the command is rejected **1712**. In some implementations, rejecting **1712** the command can include transmitting a notice of an attempted unauthorized command to supervisory personnel or law enforcement agency. If the command is determined to be authorized, the command is transmitted **1714** to the processor (e.g. **106** in FIG. **1**) and the command **1712** is performed by the lift. In some implementations, a log or journal of all extracted commands in action **1802** and the determination **1710** of the authority of the extracted commands is stored.

FIG. **19** is a flowchart of a method **1900** to control a patient-lifting-device, according to an implementation involving trig-

25

ger words. Some implementations of method **1900** include receiving audio, at block **1902**. A determination is made as to whether or not the volume of the audio is below a threshold for a predetermined amount of time, at block **1904**. The audio level being below the threshold for predetermined amount of time is interpreted to be the end of a command sequence from the operator. If the audio level is determined to be not below the threshold for the predetermined amount of time at block **1904**, method **1900** continues with receiving audio at block **1902**. If the audio level is equal to and/or greater than the audio volume threshold for the predetermined amount of time at block **1904** method **1900** continues by extracting a command from the audio, at block **1906**. In some implementations method **1900** also includes determining whether or not the command is a word or phrase in a trigger override word set, at block **1908**. Examples of a trigger override word set include the words “stop,” “wait” and “help.” If the command is determined to be in the trigger override word set at block **1908** then the command is performed at block **1910**, and/or movement of the patient-lifting-device is ceased. If the command is not determined to be in the trigger override word set at block **1908** then a determination is made as to whether or not the command is in a trigger phrase word set, at block **1912**. The trigger phrase word set includes commands such that indicate the intention by the operator to provide a functional command to the patient-lifting-device. Examples of a trigger phrase word set include “molift command,” “lift command,” and “attention.” If the command is determined to not be in the trigger phrase word set at block **1912**, method **1900** continues with receiving audio at block **1902**. If the command is determined to be in the trigger phrase word set at block **1912**, the method continues by receiving a next command, at block **1914**, and then performing the next command, at block **1916**. Examples of commands that are performed at block **1916** include “lower down,” “move down,” “move forward,” “forward,” “move backward,” “reverse,” “goto sleep,” “sleep,” “faster,” “slower,” “left,” “right,” “up,” “down,” “forward,” and “backward” or other commands to move the patient lifting device in a particular direction and/or any particular speed.

One example of the predetermined amount of time in method **1900** and method **2000** is two (2) seconds, however other implementations other amounts of time are implemented. One example of the threshold volume of audio in method **1900** is 70 dB, however other implementations of other threshold levels of audio volume are implemented. In some implementations the amount of predetermined time and/or the threshold level of audio volume can be modified through a user configuration interface.

FIG. **20** is a flowchart of a method **2000** to control a patient-lifting-device, according to an implementation involving trigger override command set words. Some implementations of method **2000** include receiving audio, at block **1902**. A determination is made as to whether or not the volume of the audio is above a threshold for at least a predetermined amount of time, at block **1904**. The audio level being above the threshold for predetermined amount of time is interpreted to indicate a possible emergency situation which might be dangerous to operate the patient-lifting apparatus. One example of the threshold volume of audio in method **1500** is 90 dB, however other implementations of other threshold levels of audio volume are implemented. If the audio level is determined to be not above the threshold for the predetermined amount of time at block **1902**, in which method **2000** continues with receiving audio at block **1902**. If the audio level is greater than the audio volume threshold for at least the predetermined amount of time at block **1904**, method **2000** continues by performing

26

a safety procedure at block **1905**. Examples of the safety procedure are stopping movement of the patient-lifting-device, reversing movement, and reversing a previous action. After performing the safety procedure at block **1905**, method **2000** continues with receiving audio at block **1902**. In some implementations the amount of predetermined time and/or the threshold level of audio volume can be modified through a user configuration interface.

FIG. **21** is a flowchart of a method **2100** to control a patient-lifting-device, according to an implementation involving disruptive audio volume. Some implementations of method **2100** include receiving an initiation signal at block **2102** and then transmitting an acknowledgment of the initiation signal at block **2104**. One example of an initiation signal is an indication of the processor or the patient-lifting-device being powered on. One example of an acknowledgment of the initiation is an audio enunciation of instructions on how to operate the system. In some implementations the instructions include a recitation of voice command instructions.

Method **2100** includes receiving a command, a trigger-phrase word-set or trigger-override word-set, at block **2106**. In some implementations, trigger-phrase word-set or trigger-override word-set is a recognition of verbiage from an audio signal. The trigger-phrase word-set or trigger-override word-set are described in conjunction with FIG. **19**. The trigger-phrase word-set or trigger-override word-set is evaluated or compared to determine if the trigger-phrase word-set or trigger-override word-set is trigger-phrase word-set, at block **2108**. If the trigger-phrase word-set or trigger-override word-set is a trigger-phrase word-set, then an acknowledgment of the trigger-phrase word-set presented and the local environment, at block **2110**. For example if the trigger-phrase word-set “Molift™ command” is received at block **2106**, then a “beep” sound is enunciated. The beep sound provides a cue to the speaker of the trigger-phrase word-set that the system understands that the user has enunciated a trigger-phrase word-set and that the speaker intends to enunciate a command for performance by the system. The command is substantially similar to the command-set **1106** of FIG. **11**.

If the comparison at block **2108** determines that the trigger-phrase word-set or trigger-override word-set is not a trigger-phrase word-set, in which case the trigger-phrase word-set or trigger-override word-set is a trigger-override word-set or a command, then an acknowledgment of the command or trigger-override word-set is presented to the local environment, at block **2112**. For example, the command or the trigger-override word-set is enunciated by a speech generation module. The presentation of the command or the trigger-override word-set at block **2112** provides an acknowledgment of the function that is to be performed by the lift. In method **2100**, performance of the command or trigger-override word-set is started at block **2114** and the command or trigger-override word-set is performed simultaneously during the enunciation representation of the command or trigger-override word-set at block **2112**. In other implementations not shown the representation or enunciation of the command or trigger-override word-set is completed at block **2112** before performance of the command begins at block **2114**.

After the command or trigger-override word-set is presented or enunciated to the user at block **2112** and performance of the command or trigger-override word-set has begun, a determination as to whether or not the command or trigger-override word-set is a command to deactivate, at block **2116**. If the command or trigger-override word-set is not a deactivation command, such as “sleep” then control is passed to block **2106**. If the command or trigger-override word-set is a deactivation command, then the method **2100** ends.

27

FIG. 22 is a flowchart of a method 2200 to update a database of authorities of a patient-lifting-device, according to an implementation. A database of authorities is a database that associates a recording a speech sample of a human with a healthcare relationship authority of control of the patient-lifting-device. The database can be accessed as a reference to determine if particular speaker has authority to direct the patient-lifting-device to perform a particular command or any commands at all.

Method 2200 includes recording a speech sample of a human, at block 2202. In some implementations, the human is someone who will or could come into contact with a patient in a healthcare facility. For example, the human is selected from the group of humans comprising human professional healthcare providers (e.g. physicians, nurses, psychiatrists/psychologists and/or counselors), human non-professional employees of a healthcare facility (e.g. receptionists and/or janitors), patients, and friends, relatives and coworkers of the patient. In other implementations, the human is not only someone who will or could come into contact with a patient in a hospital, but also is someone who works in the healthcare facility but whose job functions do not ordinarily call them into contact with any patients, such as an IT worker in the computer data processing department. The benefit of recording a speech sample of only humans who might ordinarily come into contact with a patient is that the database of authorities will be more narrowly tailored in scope to the voices that that a voice recognition system might ordinarily be called upon to analyze. The benefit of recording a speech sample of a human whose job functions do not ordinarily call them into contact with any patients is that the database of authorities will include speech samples of people who are clearly not authorized to be involved in patient care, thus providing more definitive and conclusive negative identification of authorization by a voice recognition system, which decreases to likelihood of a false positive identification of a speaker by the voice recognition system and/or a false negative identification of the speaker by the voice recognition system.

Method 2200 also includes associating the recording with a healthcare relationship authority of control of the patient-lifting-device, at block 2204. In some implementations, the healthcare relationship authority of the human to the at least one patient is selected from the group of authorities includes 1) full authority and 2) no authority. A healthcare relationship authority of full authority provides authorization of the human to exercise or command all functions of the lift. A healthcare relationship authority of no authority provides no authority of the human to exercise or command any function of the lift.

FIG. 23 is a flowchart of a method 2300 to control a device-controller of a patient-lifting-device, according to an implementation.

Method 2300 includes receiving from a voice-recognition unit, a command associated with a patient-lifting-device, at block 2302. Method 2300 also includes configuring a port to perform the command, at block 2304. The port is associated with the command. The mere configuring the port causes the patient-lifting-device to perform the command. Methods 2400 and 2500 describe more specific implementations of method 2300.

FIG. 24 is a flowchart of a method 2400 to control a device-controller of a patient-lifting-device, according to an implementation. Method 2400 is one implementation of method 2300.

Method 2400 includes receiving from a voice-recognition unit, a command associated with a patient-lifting-device, at

28

block 2302. Method 2400 also includes determining or identifying which port of the device-controller of the patient-lifting-device is associated with the command, at block 2402. In some implementations, the association between the port of the device-controller of the patient-lifting-device and the command is a direct correspondence.

Method 2400 also includes configuring the identified port in order to perform the command, at block 2404. Various techniques of configuring the port using relays are described in methods 2500 and 2600.

Some implementations of method 2400 also include overriding the configuration of the port in response to a command received from a tactile input device, such as a hand-held controller, or an input device other than a microphone and voice-recognition unit. The configuration of the port is overridden to provide higher priority to the other input device, which is helpful in some situations where the command from the other input device is considered to be more reliable and/or accurate or where the command from the other input device is designated for any reason or even arbitrarily as being the input device with the highest priority.

FIG. 25 is a flowchart of a method 2500 to control a device-controller of a patient-lifting-device, according to an implementation. Method 2500 is one implementation of method 2300.

Method 2500 includes receiving from a voice-recognition unit, a movement-command associated with a patient-lifting-device, at block 2302. The movement command can be in anyone of a number of electronic formats, such as a transient signal, a text-encoded binary representation, and/or a numerical representation encoded in binary.

In regards to the movement-command, in some implementations in which the lifting apparatus provides electrically or hydraulically actuated movement in one dimension (along a line) such as shown in the one dimensional patient-lifting-device 4500 in FIG. 45, the movement-command is one of two different commands, "up," and "down." In some implementations in which the lifting apparatus provides electrically or hydraulically actuated movement in two dimensions (along a plane) such as shown in the two dimensional patient-lifting-device 4500 in FIG. 44, the movement-command is one of four different commands, "up," "down," "forward," and "backward." In some implementations in which the lifting apparatus provides electrically or hydraulically actuated movement in three dimensions (throughout a volume), the movement-command is one of six different commands, "left," "right," "up," "down," "forward," and "backward."

Further in regard to the movement-command, in some implementations in which the lifting apparatus has a safety halt feature and that provides electrically or hydraulically actuated movement in one dimension (along a line) such as shown in the one dimensional patient-lifting-device 4500 in FIG. 45, the movement-command is one of five different commands, "up," "down," "stop," halt," and "help." The "stop," halt," and "help" commands are cessation-commands that can be enunciated by an operator to end movement of the lifting apparatus. In some implementations in which the lifting apparatus has a safety halt feature and that provides electrically or hydraulically actuated movement in two dimensions (along a plane) such as shown in the two dimensional patient-lifting-device 4400 in FIG. 44, the movement-command is one of seven different commands, "up," "down," "forward," "backward," "stop," halt," and "help." In some implementations in which the lifting apparatus has a safety halt feature and that provides electrically or hydraulically actuated movement in three dimensions (throughout a vol-

29

ume), the movement-command is one of nine different commands, "left," "right," "up," "down," "forward," "backward," "stop," "halt," and "help."

Method **2500** also includes identifying or determining which relay of a plurality of relays is associated with the movement-command, at block **2502**. The number of relays is equal to the number of movement-commands that are not "halt" or "stop." One relay for each direction of movement. For example, where the movement-commands are "up," "down," "forward," and "backward" the number of relays is four. In another example, where the movement-commands are "left," "right," "up," "down," "forward," and "backward" the number of relays is six.

In some implementations, each of the plurality of relays is a single-pole-single-throw relay. In other implementations, each of the plurality of relays is a double-pole-double-throw (DPDT) relay. In other implementations, some of the plurality of relays is a single-pole-single-throw relay and some of the plurality of relays is a DPDT relay.

Method **2500** also includes actuating the identified relay, at block **2504**. Actuating the identified relay causes a circuit to be completed or closed, in which the completed/closed circuit being associated with the movement-command. Completion/closing of the circuit that is associated with the direction of movement of the patient-lifting-device that is the same as the movement-command actuates the patient-lifting-device in accordance with the movement-command.

A normally open (NO) relay is implemented in situations where movement is actuated by completing a circuit, such as described at block **2504**. However, in other implementations where movement is actuated by opening or breaking a circuit, a normally-closed (NC) relay is used.

Some implementations of method **2500** also include override the completed circuit in response to a command received from a tactile input device, such as a hand-held controller, or an input device other than a microphone and voice-recognition unit, at block **2506**. One implementation of overriding the completed circuit is opening the circuit. The completed circuit is overridden to provide higher priority to the other input device, which is helpful in some situations where the command from the other input device is considered to be more reliable and/or accurate or the command from the other input device is designated rather arbitrarily as being the input device with the highest priority.

FIG. **26** is a flowchart of a method **2600** to control a device-controller of a patient-lifting-device, according to an implementation. Method **2600** is one implementation of method **2500**.

In method **2600**, after the movement-command is received from the voice-recognition engine, the movement-command is tested to determine or evaluate if the movement-command is a cessation-command, at block **2602**. Examples of cessation-command include "stop," "halt" and "help." If the movement-command is a cessation-command, then in some implementations, all relays are deactivated (e.g. normally-open relays are opened) at block **2604**. In other, implementations, if the movement-command is a cessation-command, then only the actuated (active) relay(s) are deactivated. If the movement-command is not a cessation-command, then the method proceeds with the next action of identifying or determining which relay of a plurality of relays is associated with the movement-command, at block **2502**, and continuing thereafter.

FIG. **27** is a flowchart of a method **2700** to control a device-controller of a patient-lifting-device, according to an implementation. Method **2700** includes receiving **2702** a sequence. The sequence represents data that originates from a source;

30

the source is selected from the group consisting of a human and the device. One example of the device is the multisensor **1106** in FIG. **11**. Some implementations of receiving **2702** includes reading a sequence of one or more sensory stimulus and reading a sequence of one or more multisensory stimulus. Some implementations of receiving **2702** includes reading a sequence of one or more sensory action and reading a sequence of one or more multisensory action. Some implementations of receiving **2702** includes reading a sequence of one or more sensory input and reading a sequence of one or more multisensory input. In one example, a sensory stimulus represents a position of an eye that relates to an action of a device.

Method **2700** also includes recording **2704** the sequence.

At least one sensory stimulus is uniquely associated to an instruction set in a dynamically configurable library/directory/table. Method **2700** includes identifying **2706** the sequence in a library/directory/table of sequences. Each sequence is associated with an instruction set. Method **2700** also includes identifying **2708** the instruction set that is associated with the sequence.

FIG. **28** is a flowchart of a method **2800** to control a device having a safety stop, according to an implementation. In method **2800**, movement of the controlled device will cease after a particular time period if no indication to continue movement is detected or received. In some implementations, system **100** defaults to stopping all movement after a duration of performance of a movement-command.

In some implementations, method **2800** is adapted for use in controlling devices in response to a command of an occupied-command-set. An occupied-command-set is a plurality of commands that are performed only when a controller device is occupied by a human or other subject that is being transported.

In some implementations, method **2800** is performed continuously starting when the controller device is powered on or otherwise available to use, until the controlled device is powered-off or otherwise becomes unavailable for use.

Some implementations of method **2800** include detecting a trigger-phrase, at block **2802**. In some implementations, the trigger-phrase-word-set includes commands that indicate the intention by the operator to provide a functional command or directive to the patient-lifting-device. Examples of a trigger-phrase-word-set include "molift command," "lift command," and "attention." Some implementations of the action at block **2802** include the method **1100** in FIG. **11**.

Thereafter, an acknowledgment of the trigger-phrase-word-set is generated and presented in the local environment, at block **1310**. For example if the trigger-phrase-word-set "Molift™ command" is received at block **1306**, then a "beep" sound is enunciated. The acknowledgement provides a cue to the speaker of the trigger-phrase-word-set that the system understands that the user has enunciated a trigger-phrase-word-set and that the speaker intends to enunciate a command for performance by the system. In other implementations, other acknowledgements other than a "beep" sound are generated and presented, such as generation of a vibration by a device that is placed adjacent to a human subject or placed adjacent to another item that is adjacent to the human subject.

Some implementations of method **2800** include starting or initiating a timer, the timer having a fixed duration or period, at block **2804**. In the duration of the timer (during execution of the timer), before the timer expires, at least one device of at least one or more input devices is monitored for receipt of a primary-command-phrase. If a primary-command-phrase is not determined to be received or the timer has not expired, at block **2806**, method **2800** continues at block **2806**. This loop

31

continues to poll until the primary-command-phrase is received or the timer expires. If a primary-command-phrase is determined to be received or the timer expires, at block **2806**, method **2800** continues at block **2808**. When the at least one or more input devices consists of at least two input devices, the two or more input devices are multisensory input devices.

In some implementations, the primary-command-phrase is a movement-command. In implementations where the device is a patient-lifting-device, and the patient-lifting-device provides electrically or hydraulically actuated movement in two dimensions (along a plane), such as shown in the two dimensional patient-lifting-device **4400** in FIG. **44**, the movement-command is one of two different commands, “up,” and “down.” In some implementations in which the patient-lifting-device provides electrically or hydraulically actuated movement in two dimensions (along a plane) such as shown in the two dimensional patient-lifting-device **4400** in FIG. **44**, the movement-command is one of four different commands, “up,” “down,” “forward,” and “backward.” In some implementations in which the patient-lifting-device provides electrically or hydraulically actuated movement in three dimensions (throughout a volume), the movement-command is one of six different commands, “left,” “right,” “up,” “down,” “forward,” and “backward.”

After a primary-command-phrase is received or the timer expires, a determination is made as to whether or not a primary-command-phrase is received, at block **2808**. If a primary-command-phrase is not received, method **2800** continues at block **2802**. Otherwise, if a primary-command-phrase is received, a process of the controlled device is initiated at block **2810**, in which the process corresponds to the primary-command-phrase. In one example of initiating a process of a controlled device, FIG. **28** shows a device-controller **2800** in which a relay is actuated to complete an electrical circuit to provide current flow to a motor to provide movement of a patient-lifting-device in accordance with a primary-command-phrase, movement-command or other command.

Some implementations of method **2800** include starting or initiating a continuance-time-period timer, the continuance-time-period timer having a fixed duration or period, at block **2812**. In the duration of the continuance-time-period timer (during execution of the continuance-time-period timer), before the continuance-time-period timer expires, at least one device of at least one or more input devices is monitored for receipt of a continuance-phrase. If a continuance-phrase is not determined to be received or the continuance-time-period timer has not expired, at block **2814**, method **2800** continues at block **2814**. This loop continues to poll until the continuance-phrase is received or the continuance-time-period timer expires. If a continuance-phrase is determined to be received or the continuance-time-period timer expires, at block **2814**, method **2800** continues at block **2816**.

Some implementations of method **2800** include after a continuance-command-phrase is received or the timer expires, a determination is made as to whether or not a continuance-command-phrase is received, at block **2816**. If a continuance-command-phrase is not received, method **2800** continues at block **2812**. Otherwise, if a continuance-command-phrase is received, a process of the controlled device initiated at block **2810**, method **2800** continues at block **2804**.

Some implementations of method **2800** include starting or initiating a timer, the timer having a fixed duration or period, at block **2818**. In the duration of the timer (during execution of the timer), before the timer expires, at least one device of at least one or more input devices is monitored for receipt of a secondary-command-phrase. If a secondary-command-phrase is not determined to be received or the timer has not

32

expired, at block **2820**, method **2800** continues at block **2820**. This loop continues to poll until the secondary-command-phrase is received or the timer expires. If a secondary-command-phrase is determined to be received or the timer expires, at block **2820**, method **2800** continues at block **2822**.

Some implementations of method **2800** include determining whether or not the secondary-command-phrase is the same as the primary-command-phrase, at block **2822**. If the secondary-command-phrase is the same as the primary-command-phrase, the method continues at block **2810**. If the secondary-command-phrase is not the same as the primary-command-phrase, then in some implementations of method **2800** include generating a trigger-phrase-required prompt and presenting the trigger-phrase-required prompt in the environment in the close vicinity of the controlled device and thereafter method **2800** continues at **2812**.

Computer storage media include volatile and nonvolatile, removable and non-removable media, implemented in any method or technology for storage of information, such as computer-readable instructions, data structures, program modules or other data. The term “computer storage media” includes, but is not limited to, RAM, ROM, EEPROM, FLASH memory or other memory technology, CD, DVD, or other optical storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic non-transitory storage devices, or any other media which can be used to store computer-intelligible information and which can be accessed by the computation resource **4702**.

FIG. **29** is a flowchart of a method of customizing systems **100** and **200**, according to an implementation. A family of controls and systems can be utilized by manufacturers and customizers. The family controls are organized into four general categories: (1) Wireless control receivers—incorporated into everyday electrical device(s) **114** by manufacturers; (2) General purpose remote and voice controls; (3) Multisensory controls and (4) Programmable circuit controls. The general purpose remote and voice controls, multisensory controls and programmable circuit controls is operable to control the wireless remote receivers. The wireless control receivers are incorporated into everyday electrical device(s) **114** by manufacturers. For example, the On/Off Controller, Servomotor Controller, Stepping Motors Controller and Digitally Controlled Potentiometers (DCP’s), all which are wireless. By simply replacing the standard on/off switch with the system, the wireless controller with a remote and its built into device is operable to adapt to any product that has an on/off component. This process to manufacture and distribute is very inexpensive. The Stepping Motors Controller could regulate the speed progression of a ceiling fan. Each Controller has a specific function using a globally unique identifier (GUID). Every device must be identifiable. Working together, the functions that are controllable are numerous. These wireless remotes will be programmed as a radio frequency device and not an IR (line of sight). The Multisensory Integrated Programmable Control (MIPC) is an important tool in developing a product accordingly. MIPC is a system of hardware and software that is operable to detect multiple sensory stimulus and other inputs and is operable to interface to control virtually any device or process on the market that is electric. An example use of the MIPC is that of a motorized wheelchair. Motorized wheelchairs are commonly controlled by a joystick device.

Method **2900** includes modeling each control system to the components as (objects) in a Visualization Modeler, at block **2092**. Modeling **2902** an object can include creating a graphical representation of the object and assigning attributes to the graphical representation. In some implementations, a wide

variety of standard bus interfaces, hardware and software tools that allow for the creation of physical circuits and related process logic strictly through its software, are integrated.

Working through a sensory stimulus event (SSE), any detected stimulus forms a voice command to pressure on a micro switch in the circuit. Thus, for simplicity's sake the stimulus enables the voice command to control the device and process. Working in conjunction with Process Definition Languages (PDL), VHDL, VHSIC, hardware description language, used as a design-entry language for field-programmable gate arrays and application-specific integrated circuits in electronic design automation of digital circuits, and a Control Process Definition (CPD), a set of data expressed in OPDL sufficient to specify all necessary aspects of a process, at block **2094**. CPD is used to state explicitly in detail the sequence of actions, extent, limits, and criteria of a process that is sufficient for the system to successfully execute the process.

A Process and Circuit Integration Modeler as a tool that enables modeling, design, analysis and generation of Control Process Definitions and related circuit synthesis to create a circuit board, the circuit chip and software, at block **2906**. The manufacturer or customizer uses process and Circuit Integration Modeler (CIM). The CIM produces a physical circuit. The 3 sensory interfaces are built into our circuit board and are accessible through software. Considering the time consuming problem of customizing a wheelchair for the individual with no movement of his hand, the system makes the accommodation relatively simple.

Method **2900** also includes interviewing the operator and testing a menu system through the blow tube and the directional movement from his head, at block **2098**. In some implementations, the customization process **2900** is flexible to the extent that the customizer is operable to create an actual control system and the individual is operable to create and modify the system on the spot through software changing actual circuits. In an independent survey, it was estimated that approximately 75% of all service providers for customized wheelchairs ordered were funded through Medicaid waivers. The cost effectiveness greatly reduces the existing dollars expended by Federal and State Medicaid and Medicare programs thereby increasing the ability to service more people.

FIG. **30** is flowchart of a process of a voice and manual controlled switch, such as switch **3600** in FIG. **36**, according to an implementation. Method **3000** includes receiving sound inputs into an audio circuit **3604**, at block **3002**, and method **3600** includes the audio circuit **3604** communicating the sound information to a voice recognition module **3606**, at block **3004**. Method **3000** includes identifying trigger phrases in the sound, at block **3006**. Once a trigger phrase is identified voice recognition module **3606** enters a command recognition mode for a pre-determined time, at block **3008**. During the command recognition mode voice recognition module **3606** monitors the input sound information with pattern recognition to identify commands "on", "light on", "off", "light off" or user specified commands, at block **3010**. If voice recognition module **3606** identifies a command phrase the module **3606** then compares the value of command phrase, to the value of the previously received command phrase or the default value of (off) if no previous command phrase is recorded. If the value of the command phrase differs from the previously received command phrase then the energized state of terminal **3608** is reversed by reversing the energized stay of transistor **3610** and in turn reversing the state of single-pole double-throw relay **3612**.

FIG. **31** is a flowchart of a method **3100** of a wireless mobile device controlling one or more controllable electrical devices that have an infrared control interface, according to an embodiment.

Method **3100** includes a smartphone (or other wireless mobile device) receiving audio speech, at block **3102**. The audio speech is associated with one of the controllable electrical devices. The audio speech is received at a microphone of the wireless mobile device. One example of the smartphone is the mobile device in FIG. **46**.

Method **3100** also includes the smartphone determining which controllable electrical device the smartphone is directed. To which controllable electrical device the smartphone is directed is determined from the screen on the smartphone that the user has selected, as described in FIG. **51-56**. A vocabulary set is selected that is specifically limited to the selected controllable electrical device. The selected vocabulary set includes data that is relevant only to the selected controllable electrical device, which is greatly helpful providing faster processing of the speech data in action **3104**, but also is greatly helpful in providing more accurate processing of the speech data in action **3104**. Using a vocabulary set that is specifically limited to the selected controllable electrical device is faster and more accurate because the vocabulary set does not include information and commands for devices other than the selected controllable electrical device, which greatly reduces the information and commands that the smartphone needs to consider, which is not only faster, but reduces the nuances that introduce ambiguity in a large vocabulary set for many more devices than the selected controllable electrical device. For example, when the selected controllable electrical device is a light that supports only the functions of ON and OFF, the selected vocabulary set for the light includes only information and commands that are relevant to the ON and OFF functions of the light, and does not include information relevant to the whole "universe" of other controllable electrical devices. Processing the vocabulary set for the light is very much faster and more accurate than processing the vocabulary for all controllable electrical devices. In one implementation, a linguist component **1616** in FIG. **16** is limited to the selected controllable electrical device.

Method **3100** also includes the smartphone performing speech recognition on the audio speech in reference to the selected vocabulary set to generate speech data, at block **3104**. Method **3100** also includes the smartphone converting speech data to an ASCII string, at block **3106**. The ASCII string represents control data of the selected controllable electrical device. Method **3100** also includes establishing a WIFI communication path with a wireless WIFI wireless router that is associated with the at least one controllable electrical device at the wireless mobile device, at block **3107**, which can be and needs to be performed at any point before action **3108**. Method **3100** also includes the smartphone sending the ASCII string to a WIFI wireless router that is associated with the at least one controllable electrical device (either through WIFI or through the Internet), at block **3108**.

Method **3100** also includes the router receiving the ASCII string from the smartphone and the router determining that at the least one controllable electrical device of the ASCII string is controlled through an infrared interface, which yields an associated infrared interface and the router determining a propriety processor that is associated with the associated infrared interface, which yields an associated proprietary processor, at block **3110**. Method **3100** also includes the router sending the ASCII string from the WIFI wireless router to the associated proprietary processor, at block **3112**.

Method **3100** also includes the associated proprietary processor receiving the ASCII string from the router and the associated proprietary processor creating a socket from the ASCII string, at block **3114**. The socket packet includes data that is relevant only to the selected controllable electrical device. Method **3100** also includes the associated proprietary processor sending the socket packet from the associated proprietary processor to the WIFI wireless router that is associated with the selected controllable electrical device, at block **3116**. The transmission of the sending has a destination address of an IP-to-IR controller that controls the selected controllable electrical device. The IP-to-IR controller is an Internet-protocol to infrared controller such as the model IP2IR manufactured by Global Cache, 160 East California Street, PO Box 1659, Jacksonville, Oreg. 97530). In some implementations, the IP-to-IR controller is capable of transceiving Internet protocol communications from and to infrared communications. In some implementations, the IP-to-IR controller is capable of only receiving Internet protocol communications and sending the communications over infrared.

For the IP2IR IP-to-IR controller manufactured by Global Cache, communication with the IP-to-IR controller is accomplished by opening a TCP socket on Port **4998**. All commands and data, with the exception of serial (RS232) data, are communicated through Port **4998**.

The ASCII string is sent using a 'sendir' command with the following syntax:

```
sendir,<connectoraddress>,<ID>,<frequency>,<repeat>,<offset>,<on1>,<off1>,<on2>,<off2>,<onN>,<offN> (where N is less than 260 or a total of 520) d
```

where;

<connectoraddress> is A connector's address is its position within a module, starting at 1 on the left, and increasing sequentially as you move to the right. A complete connector address includes the module address and the connector location in the module, separated by a colon

```
<ID> is |0|1|2|...|65535|
<frequency> is |15000|15001|...|500000| (in hertz)
<repeat> is |1|2|...|50| (the IR command is sent <repeat> times)
<offset> is |1|3|5|...|383| (used if <repeat> is greater than 1, see below)
<on1> is |1|2|...|65635| (number of pulses)
<off1> is |1|2|...|65635| (absence of pulse periods of the carrier frequency)
```

The <repeat> is the number of times an IR transmission is sent, if it is not halted early via a stopir or another IR command. Values above 50 are accepted, but IR commands are sent only the maximum 50 times. In all cases, the preamble is only sent once (see <offset> below). An <offset> applies when the <repeat> is greater than 1. For IR commands that have preambles, an <offset> is employed to avoid repeating the preamble during repeated IR timing patterns. The <offset> value indicates the location within the timing pattern to start repeating the IR command as indicated below. The <offset> will always be an odd value since a timing pattern begins with an <on> state and must end with an <off> state.

Method **3100** also includes the WIFI wireless router that is associated with the at least one controllable electrical device receiving the socket packet at from the proprietary processor; and sending the socket packet to the IP-to-IR controller, at block **3118**.

Method **3100** also includes the IP-to-IR controller receiving the socket packet and from the WIFI wireless router that is associated with the at least one controllable electrical

device and the IP-to-IR controller sending an infrared signal in accordance with the socket packet to an infrared port of the selected controllable electrical device, at block **3120**.

Method **3100** also includes the infrared port of the selected controllable infrared electrical device receiving the infrared signal in accordance with the socket packet from the IP-to-IR controller, at block **3122** and method **3100** also includes the selected controllable electrical device performing a function in accordance with the IR signal, and thus controlling the selected controllable electrical device in accordance to the audio speech, at block **3124**.

FIG. **32** is a flowchart of a method **3200** of a wireless mobile device controlling an electrical device that has an infrared control interface, according to an embodiment.

Method **3200** includes a smartphone or other wireless mobile device receiving audio speech from user through a microphone, at block **3102**. Method **3200** also includes the smartphone performing speech recognition on the audio speech to generate speech data, which generates speech data, at block **3104**. Method **3200** also includes the smartphone converting speech data to an ASCII string, at block **3106**. Method **3100** also includes establishing a WIFI communication path between the WIFI wireless router and the smartphone, at block **3107**. Method **3200** also includes the smartphone sending the ASCII string to a router (either through WIFI or through internet), at block **3108**.

Method **3200** also includes the router receiving the ASCII string from the smartphone and the router sending the ASCII string to a proprietary processor, at block **3112**.

Method **3200** also includes the proprietary processor receiving the ASCII string from the router and the proprietary processor determining that the target device is controlled through a radio frequency (RF) interface, such as a GE Smart Remote Plus Transmitter RF102TXPS, at block **3202**. Method **3200** also includes the proprietary processor setting relays of the RF interfaces based on the ASCII string, at block **3204**, and the RF controllable electrical device is operable to receive an RF signal at the RF interface **4822** of the RF controllable electrical device and operable to perform a function in accordance with the infrared signal, providing control of an IR controllable electrical device **4804** in accordance with the audio speech.

Hardware and Operating Environment

FIG. **33** is a block diagram of a voice-recognition apparatus **3300** to control a patient-lifting-apparatus, according to an implementation. The voice-recognition apparatus **3300** is one implementation of voice-recognition unit **804** in FIG. **8**. The voice-recognition apparatus **3300** receives input from any one of a number of input mediums, such as audio, and therefrom controls a patient-lifting-apparatus. The voice-recognition apparatus **3300** can fit inside the housing of conventional patient-lifting-apparatus and can communicate with and control conventional patient-lifting-apparatus using the conventional existing electrical circuitry of patient-lifting-apparatus. The voice-recognition apparatus **3300** helps improve control of the patient-lifting-apparatus by receiving input from any one of a number of input mediums, such as audio. In the example of audio, the voice-recognition apparatus **3300** improves the ease and convenience with which an operator can control the patient-lifting-apparatus by providing a voice interface to the patient-lifting-apparatus. In general, the voice-recognition apparatus **3300** improves the ease and convenience with which an operator can control the patient-lifting-apparatus by providing a command interface to the

patient-lifting-apparatus other than a handheld control device, such as the handheld control device **4426** shown in FIG. **44**.

Voice-recognition apparatus **3300** includes a microcontroller, processor or microprocessor **3302**, such as a RSC 6502 microcontroller. The 6502 is an 8-bit processor with a 16-bit address bus. The internal logic runs at the same speed as the external clock rate, and having clock speeds typically in the neighborhood of 1 or 2 MHz. The 6502 has a relatively simplistic state machine implemented by combinatorial (clockless) logic. A two phase clock (supplying two synchronizations per cycle) can thereby control the whole machine-cycle directly. The 6502 microcontroller is not sequenced by a microcode read-only-memory but uses a programmable logic array for instruction decoding and sequencing. Like most typical eight-bit microprocessors, the 6502 microcontroller does some limited overlapping of fetching and execution. The low clock frequency moderates the speed requirement of memory and peripherals attached to the 6502 microcontroller, as only about 50% of the clock cycle is available for memory access (due to the asynchronous design, this percentage varies strongly among chip versions). The 6502 microcontroller is minimalistically engineered and efficiently manufactured and therefore inexpensive. Like its precursor, the Motorola 6800 (but unlike Intel 8080 and similar microprocessors) the 6502 microcontroller has very few registers. The registers of the 6502 microcontroller include one 8-bit accumulator register (A), two 8-bit index registers (X and Y), an 8-bit processor status register (P), an 8-bit stack pointer (S), and a 16-bit program counter (PC). The subroutine call/scratchpad stack's address space is hardwired to memory page \$01, i.e. the address range \$0100-\$01FF (256-511). Software access to the stack is performed via four implied addressing mode instructions whose functions are to push or pop (pull) the accumulator or the processor status register. The same stack is also used for subroutine calls via the JSR (Jump to Subroutine) and RTS (Return from Subroutine) instructions, and for interrupt handling. The 6502 microcontroller uses the index and stack registers effectively with several addressing modes, including a fast "direct page" or "zero page" mode, similar to that found on the PDP-8, that accessed memory locations from address 0 to 255 with a single 8-bit address (saving the cycle normally required to fetch the high-order byte of the address)—code for the 6502 use the zero page much as code for other processors do have used registers. Addressing modes also include implied (1 byte instructions); absolute (3 bytes); indexed absolute (3 bytes); indexed zero-page (2 bytes); relative (2 bytes); accumulator (1); indirect,x and indirect,y (2); and immediate (2). Absolute mode is a general-purpose mode. Branch instructions use a signed 8-bit offset relative to the instruction after the branch; the numerical range -128..127 therefore translates to 128 bytes backward and 127 bytes forward from the instruction following the branch (which is 126 bytes backward and 129 bytes forward from the start of the branch instruction). Accumulator mode uses the accumulator as an effective address, and did not need any operand data. Immediate mode uses an 8-bit literal operand. The indirect modes are useful for array processing and other looping. With the % cycle "(indirect),y" mode, the 8-bit Y register is added to a 16-bit base address in zero page, located by a single byte following the opcode. As the resulting address could be anywhere in the 16-bit memory range, the Y register is a true index register, as opposed to the 6800, which had one 16-bit address register. Incrementing the index register to walk the array byte-wise took only two additional cycles. With the less frequently used "(indirect,x)" mode the effective address for the operation is found at the

zero page address formed by adding the second byte of the instruction to the contents of the X register. Using the indexed modes, the zero page effectively acted as a set of 128 additional (though very slow) address registers. The 6502 also includes a set of binary coded decimal (BCD) instructions, a feature normally implemented in software. Placing the CPU into BCD allowed numbers to be manipulated in base-10, with a set of conversion instructions to convert between base-10 and binary (base-2). For instance, with the "D" flag set, 99+1 do result in 00 and the carry flag being set. These instructions remove the need to convert numbers for display in the BASIC interpreter itself. However, this feature means other useful instructions can not be implemented easily, and is sometimes removed to make room for custom instructions. The RSC 6502 microcontroller is merely one example of microcontroller, processor or microprocessor that can be used in the voice-recognition apparatus **3300**. The RSC 6502 microcontroller has been manufactured by Conexant Systems at 4000 MacArthur Boulevard, Newport Beach, Calif.

The microcontroller, processor or microprocessor **3302** is operably coupled to a voice-recognition apparatus **3300** includes at least one input device, such as one of the devices shown in FIG. **6** including a keyboard, a synaptic reader, and/or a microphone **3304** such as shown in FIG. **33**.

And some implementations, the microcontroller, processor or microprocessor **3302** is operably coupled to a program/run switch **3306** that is set to indicate the mode that the microcontroller, processor or microprocessor **3302** is operating. When the microcontroller, processor or microprocessor **3302** is being programmed, the program/run switch **3306** is set to program. When the microcontroller, processor or microprocessor **3302** is being run, the program/run switch **3306** is set to run.

The microcontroller, processor or microprocessor **3302** is operably coupled to a power input **3306**.

In some implementations, the microcontroller, processor or microprocessor **3302** is operably coupled to a memory **3310** that stores data and programs. In some implementations the **3310** is a nonvolatile memory. In some implementations, the microcontroller, processor or microprocessor **3302** is operably coupled to a digital-to-analog (DAC) converter that generates DAC output **3312**. In some implementations, the microcontroller, processor or microprocessor **3302** is operably coupled to an audio speaker **3314**.

In other implementations, the microcontroller, processor or microprocessor **3302** includes memory. In some implementations in which the microcontroller, processor or microprocessor **3302** includes memory, a microprocessor/microcontroller/processor provides an economical wireless voice control and communications system. The microprocessor/microcontroller/processor incorporates voice recognition, infrared (IR) and radio frequency (RF) wireless protocols including Zigbee and Bluetooth wireless protocols with positional awareness and a complex programmable logic device (CPLD) interface. The microprocessor/microcontroller/processor communicates with and controls multi-sensory controls for electrical device(s) **114** from microwaves and washing machines to spacecraft. The microprocessor/microcontroller/processors are selected from both 16-bit and 32-bit devices. The microprocessor/microcontroller/processor having 16-bit radio-frequency (RF) interfaces are well-suited for applications such as wireless keyboard/mouse, wireless voice-over-IP (VoIP), remote controls, wireless gaming accessories, home and building automation applications such as alarm and security systems, automatic meter reading systems, active radio-frequency identification (RFID) systems and other monitoring and control systems.

Microprocessor/microcontroller/processors having 32-bit word-length include high performance integrated peripherals designed for real-time control applications. An optimized core of the microprocessor/microcontroller/processor performs multiple complex control algorithms at speeds necessary for demanding control applications. Integrated peripherals such as a 16-channel, 12-bit analog-to-digital conversion (ADC) running at up to 12.5 megasamples per second and high resolution pulse-width modulation (PWM) modules with 150 picosecond resolution provide sufficient bandwidth for communication with analog devices. Further including the serial peripheral interface (SPI), universal asynchronous receiver/transmitter (UART), inter-IC (I2C), campus area network (CAN), and multi-channel buffered serial port (McBSP) communication peripherals provides device control on a single microprocessor/microcontroller/processor. Applications include appliances, alternating current/direct current (AC/DC), direct current/alternating (DC/AC) and direct current/direct current (DC/DC) digital power supplies, solar inverters, digital motor control, and power line communication.

The microcontroller, processor or microprocessor **3302** is operably coupled to a lift device-controller **3316** that can perform action **2304** in FIG. **23**, actions **2402**, **2404** and **2406** in FIG. **24**, actions **2502**, **2504** and **2506** in FIG. **25** and action **2602** in FIG. **26**. The lift device-controller **3316** is electrically coupled to at least one patient-lifting-apparatus **3318**. Examples of the patient-lifting-apparatus **3318** include the two dimensional patient-lifting-device **4400** in FIG. **44** and the one dimensional patient-lifting-device **4500** in FIG. **45**. Device-controller **3500** in FIG. **35** is one implementation of the lift device-controller **3316** for a two dimensional patient-lifting-device, such as two dimensional patient-lifting-device **4400** in FIG. **44**, that implements a double-pole-double-throw (DPDT) relay for each direction of movement of the two dimensional patient-lifting-device.

In some implementations, the microcontroller, processor or microprocessor **3302** is operably coupled to a serial port **3320** through which program instructions can be loaded onto the microcontroller, processor or microprocessor **3302**.

In some implementations, the microcontroller, processor or microprocessor **3302** is operably coupled to a nonvolatile memory that stores a voice-recognition engine, such as voice-recognition engine **1600** in FIG. **16**. In the implementation shown in FIG. **33**, the nonvolatile memory is electrically erasable programmable read only memory (EEPROM) **3322**. The voice-recognition engine **3322** includes a predefined set of functions that are called during voice-recognition operations.

FIG. **34** is an electrical schematic diagram of a voice-recognition apparatus **3400** to control a patient-lifting-apparatus, according to an implementation. The voice-recognition apparatus **3400** is one implementation of voice-recognition unit **804** in FIG. **8**. The voice-recognition apparatus **3400** receives input from any one of a number of input mediums, including audio, and therefrom controls a patient-lifting-apparatus. The voice-recognition apparatus **3400** can fit inside the housing of conventional patient-lifting-apparatus and can communicate with and control the conventional patient-lifting-apparatus using the conventional existing electrical circuitry of patient-lifting-apparatus. The voice-recognition apparatus **3400** helps improve control of the patient-lifting-apparatus by receiving input from any one of a number of input mediums, including audio. In the example of audio, the voice-recognition apparatus **3400** improves the ease and convenience with which an operator can control the patient-lifting-apparatus by providing a voice interface to the patient-

lifting-apparatus. In general, the voice-recognition apparatus **3400** improves the ease and convenience with which an operator can control the patient-lifting-apparatus by providing a command interface to the patient-lifting-apparatus other than a handheld control device, such as the handheld control device **4426** shown in FIG. **44**.

Voice-recognition apparatus **3400** includes a microcontroller, processor or microprocessor **3402**, such as a RSC 6502 microcontroller. The microcontroller, processor or microprocessor **3402** includes non-volatile memory (not shown) such as Flash memory that can be electrically erased and reprogrammed. The RSC 6502 microcontroller is merely one example of a microcontroller, processor or microprocessor that can be used in the voice-recognition apparatus **3400**. The RSC 6502 microcontroller has been manufactured by Conexant Systems at 4000 MacArthur Boulevard, Newport Beach, Calif.

The microcontroller, processor or microprocessor **3402** is operably coupled to at least one input device (not shown), such as one of the devices shown in FIG. **6** including a keyboard, a synaptic reader, and/or a microphone. And some implementations, the microcontroller, processor or microprocessor **3402** is operably coupled to a program/run switch (not shown) that is set to indicate the mode that the microcontroller, processor or microprocessor **3402** is operating.

In some implementations, the microcontroller, processor or microprocessor **3402** is operably coupled to another memory (not shown) that stores data and programs. In some implementations, the microcontroller, processor or microprocessor **3402** is operably coupled to a digital-to-analog (DAC) converter that generates DAC output (not shown). In some implementations, the microcontroller, processor or microprocessor **3402** is operably coupled to an audio speaker (not shown).

In some implementations, the microprocessor/microcontroller/processor incorporates infrared (IR) and radio frequency (RF) wireless protocols including Zigbee and Bluetooth wireless protocols with positional awareness and a complex programmable logic device (CPLD) interface. The microprocessor/microcontroller/processor communicates with and controls multi-sensory controls for electrical device(s) **114** from microwaves and washing machines to spacecraft. The microprocessor/microcontroller/processor is selected from both 16-bit and 32-bit devices. The microprocessor/microcontroller/processor having 16-bit radio-frequency (RF) interfaces are well-suited for applications such as wireless keyboard/mouse, wireless voice-over-IP (VoIP), remote controls, wireless gaming accessories, home and building automation applications such as alarm and security systems, automatic meter reading systems, active radio-frequency identification (RFID) systems and other monitoring and control systems. Microprocessor/microcontroller/processors having 32-bit word-length include high performance integrated peripherals designed for real-time control applications. An optimized core of the microprocessor/microcontroller/processor performs multiple complex control algorithms at speeds necessary for demanding control applications. Integrated peripherals such as a 16-channel, 12-bit analog-to-digital conversion (ADC) running at up to 12.5 megasamples per second and high resolution pulse-width modulation (PWM) modules with 150 picosecond resolution provide sufficient bandwidth for communication with analog devices. Further including the serial peripheral interface (SPI), universal asynchronous receiver/transmitter (UART), inter-IC (I2C), campus area network (CAN), and multi-channel buffered serial port (McBSP) communication peripherals provides device control on a single microprocessor/microcon-

41

troller/processor. Applications include appliances, alternating current/direct current (AC/DC), direct current/alternating (DC/AC) and direct current/direct current (DC/DC) digital power supplies, solar inverters, digital motor control, and power line communication.

The microcontroller, processor or microprocessor 3402 is operably coupled to a lift device-controller (not shown) that can perform action 2304 in FIG. 23, actions 2402, 2404 and 2406 in FIG. 24, actions 2502, 2504 and 2506 in FIG. 25 and action 2602 in FIG. 26. The lift device-controller is electrically coupled to at least one patient-lifting-apparatus (not shown). Examples of the patient-lifting-apparatus (not shown) include the two dimensional patient-lifting-device 4400 in FIG. 44 and the one dimensional patient-lifting-device 4700 in FIG. 45. Device-controller 3500 in FIG. 35 is one implementation of the lift device-controller 3416 for a two dimensional patient-lifting-device, such as two dimensional patient-lifting-device 4400 in FIG. 44, that implements a double-pole-double-throw (DPDT) relay for each direction of movement of the two dimensional patient-lifting-device.

In some implementations, the microcontroller, processor or microprocessor 3402 is operably coupled to a serial port 3404 through which program instructions can be loaded onto the microcontroller, processor or microprocessor 3402.

In some implementations, the microcontroller, processor or microprocessor 3402 is operably coupled to a nonvolatile memory that stores a voice-recognition engine, such as voice-recognition engine 2400 in FIG. 24. In the implementation shown in FIG. 34, the nonvolatile memory is electrically erasable programmable read only memory (EEPROM) 3406. The voice-recognition engine 3406 includes a predefined set of functions that are called during voice-recognition operations.

FIG. 35 is a block diagram of a device-controller 3500 of a patient-lifting-device, according to an implementation using DPDT relays. Device-controller 3500 is one implementation of the lift device-controller 3316 in FIG. 33 for a two dimensional patient-lifting-device, such as two dimensional patient-lifting-device 4400 in FIG. 44, that implements a normally-open double-pole-double-throw (DPDT) relay for each direction of movement of the two dimensional patient-lifting-device. Two-dimensional movement consists of movement in four directions, hence device-controller 3500 consists of four normally-open DTDT relays. Other implementation of device-controller 3500 that do not have the safety features of device-controller 3500 implement single-pole-single-throw (SPST) relays.

To command movement in a particular direction, the corresponding relay is actuated. To actuate the patient-lifting-device in an upward direction, DPDT relay 3502 is actuated by setting voltage "high" (e.g. 3 volts) on pin "P2.0" 3503. When DPDT relay 3502 is actuated, the normally-open DPDT relay 3502 is closed, thereupon a positive electric current will flow from the positive terminal 3504 of the 24 volt DC battery 3506, through DPDT relay 3508, and through DPDT relay 3502 to Terminal A 3510 of lifting motor 3512 and also when DTDT relay 3502 is actuated, a negative electric current will flow from the negative terminal 3514 of the 24 volt DC battery 3506, through DPDT relay 3502 to Terminal B 3516 of lifting motor 3512, thus providing electric current to lifting motor 3512 in a polarity that will retract a line coupled to the lifting motor 3512, thereupon lifting the seat or hammock 4412.

To actuate the patient-lifting-device in a downward direction, DPDT relay 3508 is actuated by setting voltage "high" (e.g. 3 volts) on pin "P2.1" 3518. When DPDT relay 3508 is actuated, the normally-open DPDT relay 3508 becomes

42

closed, thereupon a negative electric current will flow from the negative terminal 3514 of the 24 volt DC battery 3506, through DPDT relay 3502, and through DPDT relay 3508 to Terminal A 3510 of lifting motor 3512 and also when DTDT relay 3508 is actuated, a positive electric current will flow from the positive terminal 3504 of the 24 volt DC battery 3506, through DPDT relay 3508 to Terminal B 3516 of lifting motor 3512, thus providing electric current to lifting motor 3512 in a polarity that will extend a line coupled to the lifting motor 3512, thereupon lowering the seat or hammock 4412.

Please note the safety feature in the serial wiring of DTDT relay 3502 and DPDT relay 3508. The safety feature lies in that positive electric current will flow from the positive terminal 3504 of the 24 volt DC battery 3506, through DPDT relay 3508, and through DPDT relay 3502 to Terminal A 3510 of lifting motor 3512 when DPDT relay 3508 is not actuated. Positive electric current will not flow from the positive terminal 3504 of the 24 volt DC battery 3506, through DPDT relay 3508, and through DPDT relay 3502 to Terminal A 3510 of lifting motor 3512 when DPDT relay 3508 is actuated. Therefore, if somehow both DPDT relay 3502 and DPDT relay 3508 are simultaneously actuated, no current will flow to the lifting motor 3512, thus preventing both positive electric current and negative electric from simultaneously flowing to Terminal A 3510 of lifting motor 3512 and preventing both positive electric current and negative electric from simultaneously flowing to Terminal B 3516 of lifting motor 3512.

Other implementations use other power sources in place of the 24 volt DC battery 3506.

To actuate the patient-lifting-device in a forward traversing direction, DPDT relay 3522 is actuated by setting voltage "high" (e.g. 3 volts) on pin "P2.2" 3523. When DPDT relay 3522 is actuated, the normally-open DPDT relay 3522 is closed, thereupon a positive electric current will flow from the positive terminal 3504 of the 24 volt DC battery 3506, through DPDT relay 3528, and through DPDT relay 3522 to Terminal A 3530 of traversing motor 3532 and also when DTDT relay 3522 is actuated, a negative electric current will flow from the negative terminal 3534 of the 24 volt DC battery 3506, through DPDT relay 3522 to Terminal B 3536 of traversing motor 3532, thus providing electric current to traversing motor 3532 in a polarity that will traverse in a forward direction the line coupled to the traversing motor 3532, thereupon moving the seat or hammock 4412 forward.

To actuate the patient-lifting-device in a backward direction, DPDT relay 3528 is actuated by setting voltage "high" (e.g. 3 volts) on pin "P2.3" 3538. When DPDT relay 3528 is actuated, the normally-open DPDT relay 3528 becomes closed, thereupon a negative electric current will flow from the negative terminal 3534 of the 24 volt DC battery 3506, through DPDT relay 3522, and through DPDT relay 3528 to Terminal A 3530 of traversing motor 3532 and also when DTDT relay 3528 is actuated, a positive electric current will flow from the positive terminal 3504 of the 24 volt DC battery 3506, through DPDT relay 3528 to Terminal B 3536 of traversing motor 3532, thus providing electric current to traversing motor 3532 in a polarity that will traverse in a backward direction the line coupled to the traversing motor 3532, thereupon lowering the seat or hammock 4412.

Please note the safety feature in the serial wiring of DTDT relay 3522 and DPDT relay 3528. The safety feature lies in that positive electric current will flow from the positive terminal 3504 of the 24 volt DC battery 3506, through DPDT relay 3528, and through DPDT relay 3522 to Terminal A 3530 of traversing motor 3532 when DPDT relay 3528 is not actuated. Positive electric current will not flow from the positive terminal 3504 of the 24 volt DC battery 3506, through DPDT

43

relay **3528**, and through DPDT relay **3522** to Terminal A **3530** of traversing motor **3532** when DPDT relay **3528** is actuated. Therefore, if somehow both DPDT relay **3522** and DPDT relay **3528** are simultaneously actuated, no current will flow to the traversing motor **3532**, thus preventing both positive electric current and negative electric from simultaneously flowing to Terminal A **3530** of traversing motor **3532** and preventing both positive electric current and negative electric from simultaneously flowing to Terminal B **3536** of traversing motor **3532**.

A DPDT relay consists of two separate switches that operate at the same time, each one with normally open and normally closed contact through a common connector. Each of the two contacts on the switch can be routed in different ways, depending on the position of the switch. An example of a switch is a mini-toggle switch or a switch using a push or pull control.

DPDT relay switches commonly use polarity reversal. That is why some variations of the DPDT relay, such as the cross-over switches, are internally wired for that purpose. The cross-over switches have only four terminals or connections, as opposed to six on a DPDT relay. Two connections are used for the outputs and the other two for the inputs. The switch then selects either normal or reversed polarity when connected to any direct current source such as a battery.

A DPDT relay has a single coil with two arms that move simultaneously. Inside of the DPDT relay, there are two separate single-pole-double-throw (SPDT) switch mechanisms.

FIG. **36** is an electrical schematic diagram of a voice and manual controlled switch **3600**, according to an implementation. The voice controlled and manual controlled wall switch **3600** is suitable for use in a small appliance or light switch. Microphone **3602** inputs sound information into audio circuit **3604** which in turn communicates the sound information to the voice recognition module **3606**. Voice recognition module **3606** monitors the input sound information with pattern recognition to identify trigger phrases. Once a trigger phrase is identified voice recognition module **3606** enters a command recognition mode for a pre-determined time. During the command recognition mode, the voice recognition module **3606** monitors the input sound information with pattern recognition processes to identify commands such as "on", "light on", "off", "light off" or other user specified commands. If voice recognition module **3606** identifies a command phrase then the voice recognition module **3606** compares the value of the command phrase to the value of the previously received command phrase or a default value (off) if no previous command phrase is recorded. If the value of the command phrase differs from the previously received command phrase than the energized state of terminal **3608** is reversed such as reversing the energized stay of transistor **3610** and in turn reversing the state of single-pole double-throw relay **3612**.

Some implementations of the voice and manual controlled switch **3600** also include a manual switch that controls the on/off operation of the voice and manual controlled switch **3600**. Some implementations of the voice and manual controlled switch **3600** also include a speaker **3616** that enunciates audio notifications in regards to the operations of the voice and manual controlled switch **3600**.

FIG. **37** is a mechanical diagram of a voice and manual controlled switch **3700**, according to an implementation. The voice controlled and manual controlled wall switch **3700** is suitable for use in a small appliance or light switch. Microphone **3602** receives sound information into audio circuit **3604** in FIG. **36** which in turn communicates the sound information to the voice recognition module **3606** in FIG. **36**. Some implementations of the voice and manual controlled

44

switch **3700** also include a manual switch that controls the on/off operation of the voice and manual controlled switch **3700**. Some implementations of the voice and manual controlled switch **3600** also include a speaker **3616** that enunciates audio notifications in regards to the operations of the voice and manual controlled switch **3700**.

FIG. **38** is an electrical schematic diagram of a voice controlled wall plug **3800** with manual invoice controlled circuitry, according to an implementation. The voice controlled and manual controlled wall switch **3800** is suitable for use in a small appliance or light switch. Microphone **3602** inputs sound information into audio circuit **3604** which in turn communicates the sound information to the voice recognition module RSC-4X **3802**. Voice recognition module RSC-4X **3802** monitors the input sound information with pattern recognition to identify trigger phrases. Once a trigger phrase is identified voice recognition module RSC-4X **3802** enters a command recognition mode for a pre-determined time. During the command recognition mode, the voice recognition module RSC-4X **3802** monitors the input sound information with pattern recognition processes to identify commands such as "on", "light on", "off", "light off" or other user specified commands. If voice recognition module RSC-4X **3802** identifies a command phrase then the voice recognition module **360** compares the value of the command phrase to the value of the previously received command phrase or a default value (off) if no previous command phrase is recorded. If the value of the command phrase differs from the previously received command phrase than the energized state of terminal **3608** is reversed such as reversing the energized stay of transistor **3610** and in turn reversing the state of a single-pole double-throw (SPDT) relay **3804**. One implementation of the SPDT relay **3804** is a G5LE-1-E-DD5 SPDT 120V-16A 5V coil.

The voice and manual controlled switch **3800** also includes one or more wall outlet plug(s) **3806** and **3808**. In implementations that include a plurality of wall out plugs, the plugs are operably coupled in parallel, such as shown in FIG. **38**.

Some implementations of the voice and manual controlled switch **3800** also include a manual switch that controls the on/off operation of the voice and manual controlled switch **3800**. Some implementations of the voice and manual controlled switch **3800** also include a speaker **3616** that enunciates audio notifications in regards to the operations of the voice and manual controlled switch **3800**.

FIG. **39** is a mechanical diagram of a voice controlled wall plug **3900** with manual invoice controlled circuitry, according to an implementation. The voice controlled and manual controlled wall switch **3900** is suitable for use in a small appliance or light switch. Microphone **3602** receives sound information into audio circuit **3604** in FIG. **38** which in turn communicates the sound information to the voice recognition module RSC-4X **3802** in FIG. **39**. Some implementations of the voice and manual controlled switch **3900** also include a manual switch that controls the on/off operation of the voice and manual controlled switch **3900**. Some implementations of the voice and manual controlled switch **3800** also include a speaker **3616** that enunciates audio notifications in regards to the operations of the voice and manual controlled switch **3900**.

FIG. **40** is an electrical schematic diagram of a voice and manual controlled light switch **4000** with manual and invoice controlled dimmer circuitry, according to an implementation. The voice controlled and manual controlled wall switch **4000** is suitable for use in a small appliance or light switch. Microphone **3602** inputs sound information into audio circuit **3604** which in turn communicates the sound information to the

voice recognition module RSC-4X **3802**. Voice recognition module RSC-4X **3802** monitors the input sound information with pattern recognition to identify trigger phrases. Once a trigger phrase is identified voice recognition module RSC-4X **3802** enters a command recognition mode for a pre-determined time. During the command recognition mode, the voice recognition module RSC-4X **3802** monitors the input sound information with pattern recognition processes to identify commands such as “on”, “light on”, “off”, “light off” or other user specified commands. If voice recognition module RSC-4X **3802** identifies a command phrase then the voice recognition module **4000** compares the value of the command phrase to the value of the previously received command phrase or a default value (off) if no previous command phrase is recorded. If the value of the command phrase differs from the previously received command phrase than the energized state of terminal **3608** is reversed such as reversing the energized stay of transistor **3610** and in turn reversing the state of single-pole double-throw relay **3804**. One implementation of the SPDT relay **3804** is a G5LE-1-E-DD5 SPDT 120V-16A 5V coil. The voice recognition module RSC-4X **3802** is operably coupled to, and controls, a variable resistor **4002** that is operably coupled to, and controls, a dimmer circuit **4004**.

Some implementations of the voice and manual controlled switch **4000** also include a manual switch that controls the on/off operation of the voice and manual controlled switch **4000**. Some implementations of the voice and manual controlled switch **4000** also include a speaker **3616** that enunciates audio notifications in regards to the operations of the voice and manual controlled switch **4000**.

FIG. **41** is a mechanical diagram of a voice and manual controlled light switch **4100** with manual and invoice controlled dimmer circuitry, according to an implementation. The voice controlled and manual controlled wall switch **4100** is suitable for use in a small appliance or light switch. Microphone **3602** receives sound information into audio circuit **3604** in FIG. **38** which in turn communicates the sound information to the voice recognition module RSC-4X **3802** in FIG. **40**. Some implementations of the voice and manual controlled switch **4100** also include a manual switch that controls the on/off operation of the voice and manual controlled switch **4100**. Some implementations of the voice and manual controlled switch **4000** also include a speaker **3616** that enunciates audio notifications in regards to the operations of the voice and manual controlled switch **4100**.

FIG. **42** is an electrical schematic diagram of a voice controlled wall plug **4200** with manual and voice controlled dimmer circuitry, according to an implementation. The voice controlled and manual controlled wall switch **4200** is suitable for use in a small appliance or light switch. Microphone **3602** inputs sound information into audio circuit **3604** which in turn communicates the sound information to the voice recognition module RSC-4X **3802**. Voice recognition module RSC-4X **3802** monitors the input sound information with pattern recognition to identify trigger phrases. Once a trigger phrase is identified voice recognition module RSC-4X **3802** enters a command recognition mode for a pre-determined time. During the command recognition mode, the voice recognition module RSC-4X **3802** monitors the input sound information with pattern recognition processes to identify commands such as “on”, “light on”, “off”, “light off” or other user specified commands. If voice recognition module RSC-4X **3802** identifies a command phrase then the voice recognition module **4200** compares the value of the command phrase to the value of the previously received command phrase or a default value (off) if no previous command phrase is recorded. If the value of the command phrase differs from

the previously received command phrase than the energized state of terminal **3608** is reversed such as reversing the energized stay of transistor **3610** and in turn reversing the state of single-pole double-throw relay **3804**. One implementation of the SPDT relay **3804** is a G5LE-1-E-DD5 SPDT 120V-16A 5V coil. The voice recognition module RSC-4X **3802** is operably coupled to, and controls, a variable resistor **4002** that is operably coupled to, and controls, a dimmer circuit **4004**.

The voice controlled wall plug **4200** also includes one or more wall outlet plug(s) **3806** and **3808**. In implementations that include a plurality of wall out plugs, the plugs are operably coupled in parallel, such as shown in FIG. **42**.

Some implementations of the voice and manual controlled switch **4300** also include a manual switch that controls the on/off operation of the voice and manual controlled switch **4200**. Some implementations of the voice and manual controlled switch **4200** also include a speaker **3616** that enunciates audio notifications in regards to the operations of the voice and manual controlled switch **4200**.

FIG. **43** is a mechanical diagram of a voice controlled wall plug **4300** with manual and voice controlled dimmer circuitry, according to an implementation. The voice controlled and manual controlled wall switch **4300** is suitable for use in a small appliance or light switch. Microphone **3602** receives sound information into audio circuit **3604** in FIG. **42** which in turn communicates the sound information to the voice recognition module RSC-4X **3802** in FIG. **42**. Some implementations of the voice and manual controlled switch **4300** also include a manual switch that controls the on/off operation of the voice and manual controlled switch **4300**. Some implementations of the voice and manual controlled switch **4300** also include a speaker **3616** that enunciates audio notifications in regards to the operations of the voice and manual controlled switch **4300**.

FIG. **44** is a block diagram of a two dimensional patient-lifting-device **4400**, according to an implementation that is specifically adapted for lifting a patient out of bed. Patient-lifting-device **4400** includes vertical main supports **4402** and **4404** that are optionally supported by wheels **4406** and **4408** for movement on the ground. Patient-lifting-device **4400** also includes a horizontal support **4410** that is fixedly attached to the vertical main supports **4402** and **4404**. In the implementation shown in FIG. **44**, a seat or hammock **4412** is attached to the horizontal support **4410** via lines **4414**, **4416**, **4418** and **4420**, although other implementations of the seat or hammock **4412** are well-known. An electric or hydraulic control box **4422** is slidably attached to the horizontal support **4410** through a rail (not shown) and the lines **4414**, **4416**, **4418** and **4420** are attached to the control box **4422** through a line **4424**. The control box **4422** causes the line **4424** to be extended or retracted. A patient is placed in the seat or hammock **4412** for movement. As the line **4424** is extended, the horizontal support **4410** is lowered upward, thus causing the patient in the hammock or seat **4412** to move downward. As the traversal arm **4412** is retracted, the line **4424** is moved upward, thus causing the patient in the hammock or seat **4412** to move upwards. In addition the control box **4422** is operable to move horizontally along the horizontal support **4410**.

In some implementations, the control box **4422** includes the various apparatus and systems described in this application that provide control of the patient-lifting-device **4400** from various stimulus such as audio voice input. Examples of the various apparatus and systems that are included in the control box **4422** include the command interface unit **102**, processor **106** and/or device controller **110** in FIG. **1** and FIG. **2**, the keyboard data receiver **602**, voice data receiver **604** and/or a synaptic data receiver **606** in FIG. **6**, the microphone

802 and or voice-recognition unit 804 in FIG. 8, the device configuration user interface 902 and/or the modifiable logic circuit 904 in FIG. 9, the electrical devices in FIG. 33-37, and other tangible systems that perform methods 1700, 1800, 1900, 2000, 2100, 2200, 2300, 2400, 2500 and/or 2600.

In some implementations, two dimensional patient-lifting-device 4400 includes a handheld control device 4426 that is electrically coupled to the control box 4422 via a line 4428, the handheld control device providing signals that directs movement of the line 4424 and movement of the control box 4422 along the horizontal support 4410. In some implementations, control initiated from the handheld control device 4426 overrides control initiated from other input means.

Some implementations of the two dimensional patient-lifting-device 4400 include a charging unit (not shown) in the horizontal support 4410 and/or the control box 4422 to provide power for recharging a battery. The battery can be mounted either in the control box 4422 or the horizontal support 4410. The charging unit is electrically coupled to a power cord having male prongs on the other end from the charging unit that are suitable to plug into a standard residential electrical wall outlet female receptacle.

Some implementations of the two dimensional patient-lifting-device 4400 are a portable lift that fits in doorways.

FIG. 45 is a block diagram of a one dimensional patient-lifting-device 4500, according to an implementation that is specifically adapted for lifting a patient in and out of a pool. Patient-lifting-device 4500 includes a vertical main support 4502 that is anchored or otherwise firmly attached to the ground 4504. Patient-lifting-device 4500 also includes a lifting arm 4506 that is rotatably attached to the vertical main support 4502. A seat or hammock 4508 is attached to the lifting arm 4506 via a line 4510. A patient is placed in the seat or hammock 4508 for movement. A traversal arm 4512 is rotatably attached to the vertical main support 4502 through a rotatable joint 4514. The traversal arm 4512 is also rotatably and slideably coupled to the lifting arm 4506 through joint 4516. An electric or hydraulic actuator 4518 is attached to the traversal arm 4512. The actuator 4518 causes the traversal arm 4512 to be extended or retracted. As the traversal arm 4512 is extended, the lifting arm 4506 is pushed upward, thus moving the patient in the hammock or seat 4508 to move upwards. As the traversal arm 4512 is retracted, the lifting arm 4506 is moved downward, thus moving the patient in the hammock or seat 4508 to move downwards.

The patient-lifting-device 4500 also includes a control box 4520. In some implementations such as shown in FIG. 45, the control box 4520 is mounted to the vertical main support 4502 although in other implementations the control box 4520 is located elsewhere. In some implementations such as shown in FIG. 45, the control box 4520 includes the various apparatus and systems described elsewhere in this application that provide control of the patient-lifting-device 4500 are various stimulus such as audio voice input. Examples of the various apparatus and systems that are included in the control box 4520 include the command interface unit 102, processor 106 and/or device controller 110 in FIG. 1 and FIG. 2, the keyboard data receiver 602, voice data receiver 604 and/or a synaptic data receiver 606 in FIG. 6, the microphone 802 and or voice-recognition unit 804 in FIG. 8, the device configuration user interface 902 and/or the modifiable logic circuit 904 in FIG. 9, the electrical devices in FIG. 33-37 and other tangible systems that perform methods 1700-3300.

FIG. 46 is a block diagram of a mobile device 4600, according to an implementation. The mobile device 4600 may also have the capability to allow voice communication. Depending on the functionality provided by the mobile

device, it may be referred to as a data messaging device, a two-way pager, a cellular telephone with data messaging capabilities, a wireless Internet appliance, or a data communication device (with or without telephony capabilities).

Mobile device 4600 is one implementation of Bluetooth-capable cell phone 1420 in FIG. 14. The mobile device 4600 includes a number of components such as a main processor 4602 that controls the overall operation of the mobile device 4600. Communication functions, including data and voice communications, are performed through a communication subsystem 4604. The communication subsystem 4604 receives messages from and sends messages to wireless networks 4605. In other implementations of the mobile device 4600, the communication subsystem 4604 can be configured in accordance with the Global System for Mobile Communication (GSM), General Packet Radio Services (GPRS), Enhanced Data GSM Environment (EDGE), Universal Mobile Telecommunications Service (UMTS), data-centric wireless networks, voice-centric wireless networks, and dual-mode networks that can support both voice and data communications over the same physical base stations. Combined dual-mode networks include, but are not limited to, Code Division Multiple Access (CDMA) or CDMA2000 networks, GSM/GPRS networks (as mentioned above), and future third-generation (3G) networks like EDGE and UMTS. Some other examples of data-centric networks include Mobitex™ and DataTAC™ network communication systems. Examples of other voice-centric data networks include Personal Communication Systems (PCS) networks like GSM and Time Division Multiple Access (TDMA) systems.

The wireless link connecting the communication subsystem 4604 with the wireless network 4605 represents one or more different Radio Frequency (RF) channels. With newer network protocols, these channels are capable of supporting both circuit switched voice communications and packet switched data communications.

The main processor 4602 also interacts with additional subsystems such as a Random Access Memory (RAM) 4606, a flash memory 4608, a display 4610, an auxiliary input/output (I/O) subsystem 4612, a data port 4614, a keyboard 4616, a speaker 4618, a microphone 4620, short-range communications 4622 and other device subsystems 4624. In some implementations, the flash memory 4608 includes a hybrid femtocell/Wi-Fi protocol stack 4609. The stack 4609 supports authentication and authorization between the mobile device 4600 into a shared Wi-Fi network and both a 3G and 4G mobile networks.

Some of the subsystems of the mobile device 4600 perform communication-related functions, whereas other subsystems may provide "resident" or on-device functions. By way of example, the display 4610 and the keyboard 4616 may be used for both communication-related functions, such as entering a text message for transmission over the wireless network 4605, and device-resident functions such as a calculator or task list.

The mobile device 4600 can transmit and receive communication signals over the wireless network 4605 after required network registration or activation procedures have been completed. Network access is associated with a subscriber or user of the mobile device 4600. To identify a subscriber, the mobile device 4600 requires a SIM/RUIM card 4626 (i.e. Subscriber Identity Module or a Removable User Identity Module) to be inserted into a SIM/RUIM interface 4628 in order to communicate with a network. The SIM card or RUIM 4626 is one type of a conventional "smart card" that can be used to identify a subscriber of the mobile device 4600 and to personalize the mobile device 4600, among other things.

Without the SIM card **4626**, the mobile device **4600** is not fully operational for communication with the wireless network **4605**. By inserting the SIM card/RUIM **4626** into the SIM/RUIM interface **4628**, a subscriber can access all subscribed services. Services may include: web browsing and messaging such as e-mail, voice mail, Short Message Service (SMS), and Multimedia Messaging Services (MMS). More advanced services may include: point of sale, field service and sales force automation. The SIM card/RUIM **4626** includes a processor and memory for storing information. Once the SIM card/RUIM **4626** is inserted into the SIM/RUIM interface **4628**, it is coupled to the main processor **4602**. In order to identify the subscriber, the SIM card/RUIM **4626** can include some user parameters such as an International Mobile Subscriber Identity (IMSI). An advantage of using the SIM card/RUIM **4626** is that a subscriber is not necessarily bound by any single physical mobile device. The SIM card/RUIM **4626** may store additional subscriber information for a mobile device as well, including datebook (or calendar) information and recent call information. Alternatively, user identification information can also be programmed into the flash memory **4608**.

The mobile device **4600** is a battery-powered device and includes a battery interface **4632** for receiving one or more rechargeable batteries **4630**. In one or more implementations, the battery **4630** can be a smart battery with an embedded microprocessor. The battery interface **4632** is coupled to a regulator **4633**, which assists the battery **4630** in providing power $V+$ to the mobile device **4600**. Although current technology makes use of a battery, future technologies such as micro fuel cells may provide the power to the mobile device **4600**.

The mobile device **4600** also includes an operating system **4634** and software components **4636** to **4646** which are described in more detail below. The operating system **4634** and the software components **4636** to **4646** that are executed by the main processor **4602** are typically stored in a persistent store such as the flash memory **4608**, which may alternatively be a read-only memory (ROM) or similar storage element (not shown). Those skilled in the art will appreciate that portions of the operating system **4634** and the software components **4636** to **4646**, such as specific device applications, or parts thereof, may be temporarily loaded into a volatile store such as the RAM **4606**. Other software components can also be included.

The subset of software applications **4636** that control basic device operations, including data and voice communication applications, will normally be installed on the mobile device **4600** during its manufacture. Other software applications include a message application **4638** that can be any suitable software program that allows a user of the mobile device **4600** to transmit and receive electronic messages. Various alternatives exist for the message application **4638** as is well known to those skilled in the art. Messages that have been sent or received by the user are typically stored in the flash memory **4608** of the mobile device **4600** or some other suitable storage element in the mobile device **4600**. In one or more implementations, some of the sent and received messages may be stored remotely from the device **4600** such as in a data store of an associated host system with which the mobile device **4600** communicates.

The software applications can further include a device state module **4640**, a Personal Information Manager (PIM) **4642**, and other suitable modules (not shown). The device state module **4640** provides persistence, i.e. the device state module **4640** ensures that important device data is stored in per-

sistent memory, such as the flash memory **4608**, so that the data is not lost when the mobile device **4600** is turned off or loses power.

The PIM **4642** includes functionality for organizing and managing data items of interest to the user, such as, but not limited to, e-mail, contacts, calendar events, voice mails, appointments, and task items. A PIM application has the ability to transmit and receive data items via the wireless network **4605**. PIM data items may be seamlessly integrated, synchronized, and updated via the wireless network **4605** with the mobile device subscriber's corresponding data items stored and/or associated with a host computer system. This functionality creates a mirrored host computer on the mobile device **4600** with respect to such items. This can be particularly advantageous when the host computer system is the mobile device subscriber's office computer system.

The mobile device **4600** also includes a connect module **4644**, and an IT policy module **4646**. The connect module **4644** implements the communication protocols that are required for the mobile device **4600** to communicate with the wireless infrastructure and any host system, such as an enterprise system, with which the mobile device **4600** is authorized to interface. Examples of a wireless infrastructure and an enterprise system are given in FIGS. **21** and **22**, which are described in more detail below.

The connect module **4644** includes a set of APIs that can be integrated with the mobile device **4600** to allow the mobile device **4600** to use any number of services associated with the enterprise system. The connect module **4644** allows the mobile device **4600** to establish an end-to-end secure, authenticated communication pipe with the host system. A subset of applications for which access is provided by the connect module **4644** can be used to pass IT policy commands from the host system to the mobile device **4600**. This can be done in a wireless or wired manner. These instructions can then be passed to the IT policy module **4646** to modify the configuration of the device **4600**. Alternatively, in some cases, the IT policy update can also be done over a wired connection.

The IT policy module **4646** receives IT policy data that encodes the IT policy. The IT policy module **4646** then ensures that the IT policy data is authenticated by the mobile device **4600**. The IT policy data can then be stored in the flash memory **4606** in its native form. After the IT policy data is stored, a global notification can be sent by the IT policy module **4646** to all of the applications residing on the mobile device **4600**. Applications for which the IT policy may be applicable then respond by reading the IT policy data to look for IT policy rules that are applicable.

The IT policy module **4646** can include a parser **4647**, which can be used by the applications to read the IT policy rules. In some cases, another module or application can provide the parser. Grouped IT policy rules, described in more detail below, are retrieved as byte streams, which are then sent (recursively) into the parser to determine the values of each IT policy rule defined within the grouped IT policy rule. In one or more implementations, the IT policy module **4646** can determine which applications are affected by the IT policy data and transmit a notification to only those applications. In either of these cases, for applications that are not being executed by the main processor **4602** at the time of the notification, the applications can call the parser or the IT policy module **4646** when they are executed to determine if there are any relevant IT policy rules in the newly received IT policy data.

All applications that support rules in the IT Policy are coded to know the type of data to expect. For example, the value that is set for the "WEP User Name" IT policy rule is

known to be a string; therefore the value in the IT policy data that corresponds to this rule is interpreted as a string. As another example, the setting for the "Set Maximum Password Attempts" IT policy rule is known to be an integer, and therefore the value in the IT policy data that corresponds to this rule is interpreted as such.

After the IT policy rules have been applied to the applicable applications or configuration files, the IT policy module 4646 sends an acknowledgement back to the host system to indicate that the IT policy data was received and successfully applied.

Other types of software applications can also be installed on the mobile device 4600. These software applications can be third party applications, which are added after the manufacture of the mobile device 4600. Examples of third party applications include games, calculators, utilities, etc.

The additional applications can be loaded onto the mobile device 4600 through at least one of the wireless network 4605, the auxiliary I/O subsystem 4612, the data port 4614, the short-range communications subsystem 4622, or any other suitable device subsystem 4624. This flexibility in application installation increases the functionality of the mobile device 4600 and may provide enhanced on-device functions, communication-related functions, or both. For example, secure communication applications may enable electronic commerce functions and other such financial transactions to be performed using the mobile device 4600.

The data port 4614 enables a subscriber to set preferences through an external device or software application and extends the capabilities of the mobile device 4600 by providing for information or software downloads to the mobile device 4600 other than through a wireless communication network. The alternate download path may, for example, be used to load an encryption key onto the mobile device 4600 through a direct and thus reliable and trusted connection to provide secure device communication.

The data port 4614 can be any suitable port that enables data communication between the mobile device 4600 and another computing device. The data port 4614 can be a serial or a parallel port. In some instances, the data port 4614 can be a USB port that includes data lines for data transfer and a supply line that can provide a charging current to charge the battery 4630 of the mobile device 4600.

The short-range communications subsystem 4622 provides for communication between the mobile device 4600 and different systems or devices, without the use of the wireless network 4605. For example, the subsystem 4622 may include an infrared device and associated circuits and components for short-range communication. Examples of short-range communication standards include standards developed by the Infrared Data Association (IrDA), Bluetooth, and the 802.11 family of standards developed by IEEE.

Bluetooth is a wireless technology standard for exchanging data over short distances (using short-wavelength radio transmissions in the ISM band from 2400-2480 MHz) from fixed and mobile devices, creating personal area networks (PANs) with high levels of security. Created by telecom vendor Ericsson in 1994, Bluetooth was originally conceived as a wireless alternative to RS-232 data cables. It can connect several devices, overcoming problems of synchronization. Bluetooth operates in the range of 2400-2483.5 MHz (including guard bands), which is in the globally unlicensed Industrial, Scientific and Medical (ISM) 2.4 GHz short-range radio frequency band. Bluetooth uses a radio technology called frequency-hopping spread spectrum. The transmitted data is divided into packets and each packet is transmitted on one of the 79 designated Bluetooth channels. Each channel has a band-

width of 1 MHz. The first channel starts at 2402 MHz and continues up to 2480 MHz in 1 MHz steps. It usually performs 1600 hops per second, with Adaptive Frequency-Hopping (AFH) enabled. Originally Gaussian frequency-shift keying (GFSK) modulation was the only modulation scheme available; subsequently, since the introduction of Bluetooth 2.0+EDR, $\pi/4$ -DQPSK and 8DPSK modulation may also be used between compatible devices. Devices functioning with GFSK are said to be operating in basic rate (BR) mode where an instantaneous data rate of 1 Mbit/s is possible. The term Enhanced Data Rate (EDR) is used to describe $\pi/4$ -DPSK and 8DPSK schemes, each giving 2 and 3 Mbit/s respectively. The combination of these (BR and EDR) modes in Bluetooth radio technology is classified as a "BR/EDR radio". Bluetooth is a packet-based protocol with a master-slave structure. One master may communicate with up to 7 slaves in a piconet; all devices share the master's clock. Packet exchange is based on the basic clock, defined by the master, which ticks at 312.5 μ s intervals. Two clock ticks make up a slot of 625 μ s; two slots make up a slot pair of 1250 μ s. In the simple case of single-slot packets the master transmits in even slots and receives in odd slots; the slave, conversely, receives in even slots and transmits in odd slots. Packets may be 1, 3 or 5 slots long but in all cases the master transmit will begin in even slots and the slave transmit in odd slots. A master Bluetooth device can communicate with a maximum of seven devices in a piconet (an ad-hoc computer network using Bluetooth technology), though not all devices reach this maximum. The devices can switch roles, by agreement, and the slave can become the master (for example, a headset initiating a connection to a phone will necessarily begin as master, as initiator of the connection; but may subsequently prefer to be slave). The Bluetooth Core Specification provides for the connection of two or more piconets to form a scatternet, in which certain devices simultaneously play the master role in one piconet and the slave role in another. At any given time, data can be transferred between the master and one other device (except for the little-used broadcast mode. The master chooses which slave device to address; typically, it switches rapidly from one device to another in a round-robin fashion. Since it is the master that chooses which slave to address, whereas a slave is (in theory) supposed to listen in each receive slot, being a master is a lighter burden than being a slave. Being a master of seven slaves is possible; being a slave of more than one master is difficult. Many of the services offered over Bluetooth can expose private data or allow the connecting party to control the Bluetooth device. For security reasons it is necessary to be able to recognize specific devices and thus enable control over which devices are allowed to connect to a given Bluetooth device. At the same time, it is useful for Bluetooth devices to be able to establish a connection without user intervention (for example, as soon as they are in range). To resolve this conflict, Bluetooth uses a process called bonding, and a bond is created through a process called pairing. The pairing process is triggered either by a specific request from a user to create a bond (for example, the user explicitly requests to "Add a Bluetooth device"), or it is triggered automatically when connecting to a service where (for the first time) the identity of a device is required for security purposes. These two cases are referred to as dedicated bonding and general bonding respectively. Pairing often involves some level of user interaction; this user interaction is the basis for confirming the identity of the devices. Once pairing successfully completes, a bond will have been formed between the two devices, enabling those two devices to connect to each other in the future without requiring the pairing process in order to confirm the identity of the devices.

When desired, the bonding relationship can later be removed by the user. Secure Simple Pairing (SSP): This is required by Bluetooth v2.1, although a Bluetooth v2.1 device may only use legacy pairing to interoperate with a v2.0 or earlier device. Secure Simple Pairing uses a form of public key cryptography, and some types can help protect against man in the middle, or MITM attacks. SSP has the following characteristics: Just works: As implied by the name, this method just works. No user interaction is required; however, a device may prompt the user to confirm the pairing process. This method is typically used by headsets with very limited capabilities, and is more secure than the fixed PIN mechanism which is typically used for legacy pairing by this set of limited devices. This method provides no man in the middle (MITM) protection. Numeric comparison: If both devices have a display and at least one can accept a binary Yes/No user input, they may use Numeric Comparison. This method displays a 6-digit numeric code on each device. The user should compare the numbers to ensure they are identical. If the comparison succeeds, the user(s) should confirm pairing on the device(s) that can accept an input. This method provides MITM protection, assuming the user confirms on both devices and actually performs the comparison properly. Passkey Entry: This method may be used between a device with a display and a device with numeric keypad entry (such as a keyboard), or two devices with numeric keypad entry. In the first case, the display is used to show a 6-digit numeric code to the user, who then enters the code on the keypad. In the second case, the user of each device enters the same 6-digit number. Both of these cases provide MITM protection. Out of band (OOB): This method uses an external means of communication, such as Near Field Communication (NFC) to exchange some information used in the pairing process. Pairing is completed using the Bluetooth radio, but requires information from the OOB mechanism. This provides only the level of MITM protection that is present in the OOB mechanism. SSP is considered simple for the following reasons: In most cases, it does not require a user to generate a passkey. For use-cases not requiring MITM protection, user interaction can be eliminated. For numeric comparison, MITM protection can be achieved with a simple equality comparison by the user. Using OOB with NFC enables pairing when devices simply get close, rather than requiring a lengthy discovery process.

In use, a received signal such as a text message, an e-mail message, or web page download will be processed by the communication subsystem **4604** and input to the main processor **4602**. The main processor **4602** will then process the received signal for output to the display **4610** or alternatively to the auxiliary I/O subsystem **4612**. A subscriber may also compose data items, such as e-mail messages, for example, using the keyboard **4616** in conjunction with the display **4610** and possibly the auxiliary I/O subsystem **4612**. The auxiliary subsystem **4612** may include devices such as: a touch screen, mouse, track ball, infrared fingerprint detector, or a roller wheel with dynamic button pressing capability. The keyboard **4616** is preferably an alphanumeric keyboard and/or telephone-type keypad. However, other types of keyboards may also be used. A composed item may be transmitted over the wireless network **4605** through the communication subsystem **4604**.

For voice communications, the overall operation of the mobile device **4600** is substantially similar, except that the received signals are output to the speaker **4618**, and signals for transmission are generated by the microphone **4620**. Alternative voice or audio I/O subsystems, such as a voice message recording subsystem, can also be implemented on the mobile device **4600**. Although voice or audio signal out-

put is accomplished primarily through the speaker **4618**, the display **4610** can also be used to provide additional information such as the identity of a calling party, duration of a voice call, or other voice call related information.

Referring now to FIG. **47**, a block diagram of the communication-subsystem component **4604** is shown, according to an implementation. The communication subsystem **4604** includes a receiver **4700**, a transmitter **4702**, as well as associated components such as one or more embedded or internal antenna elements **4704** and **4706**, Local Oscillators (LOs) **4708**, and a processing module such as a Digital Signal Processor (DSP) **4710**. The particular implementation of the communication subsystem **4604** is dependent upon the communication wireless network **4605** with which the mobile device **4600** is intended to operate. Thus, it should be understood that the implementation illustrated in FIG. **47** serves only as one example.

Signals received by the antenna **4704** through the wireless network **4605** are input to the receiver **4700**, which may perform such common receiver functions as signal amplification, frequency down conversion, filtering, channel selection, and analog-to-digital (A/D) conversion. A/D conversion of a received signal allows more complex communication functions such as demodulation and decoding to be performed in the DSP **4710**. In a similar manner, signals to be transmitted are processed, including modulation and encoding, by the DSP **4710**. These DSP-processed signals are input to the transmitter **4702** for digital-to-analog (D/A) conversion, frequency up conversion, filtering, amplification and transmission over the wireless network **4605** via the antenna **4706**. The DSP **4710** not only processes communication signals, but also provides for receiver and transmitter control. For example, the gains applied to communication signals in the receiver **4700** and the transmitter **4702** may be adaptively controlled through automatic gain control algorithms implemented in the DSP **4710**.

The wireless link between the mobile device **4600** and the wireless network **4605** can contain one or more different channels, typically different RF channels, and associated protocols used between the mobile device **4600** and the wireless network **4605**. An RF channel is a limited resource that must be conserved, typically due to limits in overall bandwidth and limited battery power of the mobile device **4600**.

When the mobile device **4600** is fully operational, the transmitter **4702** is typically keyed or turned on only when it is transmitting to the wireless network **4605** and is otherwise turned off to conserve resources. Similarly, the receiver **4700** is periodically turned off to conserve power until the receiver **4700** is needed to receive signals or information (if at all) during designated time periods.

FIG. **48** is a block diagram of a system **4800** that is operable to control one or more controllable infrared electrical devices from audio speech, the system operable to control the at least one controllable infrared device through a wireless communication path, according to an implementation.

System **4800** includes a microphone **4620** of a wireless mobile device (smartphone) **4600** that is operable to receive audio speech **4802**. The audio speech **4802** is associated with the IR controllable electrical device **4804**. The IR controllable electrical device **4804** is an electrical device that is controllable via external infrared signal(s).

The wireless mobile device **4600** also includes a speech recognition engine **4806** that is operable to generate speech data **4808** that is associated with a vocabulary set **4810** of the IR controllable electrical device **4804** from the audio speech at the wireless mobile device **4600**. The vocabulary set **4810** of the IR controllable electrical device **4804** is a set of vocabu-

55

lary that includes speech patterns of trigger phrases that are relevant to the IR controllable electrical device **4804**. Speech patterns of trigger phrases that are irrelevant to the IR controllable electrical device **4804** are not included in the vocabulary set **4810** of the IR controllable electrical device **4804**. For example, when the IR controllable electrical device **4804** is a light, the vocabulary set **4810** of the IR controllable electrical device **4804** includes only trigger phrases “on”, “light on”, “off” and “light off”, and the vocabulary set **4810** of the IR controllable electrical device **4804** excludes speech patterns of all other trigger phrases. In another example, when the IR controllable electrical device **4804** is a patient lift, the vocabulary set **4810** of the IR controllable electrical device **4804** includes only trigger phrases “lower down,” “move down,” “move forward,” “forward,” “move backward,” “reverse,” “goto sleep,” “sleep,” “faster,” “slower,” “left,” “right,” “up,” “down,” “forward,” and “backward”, and the vocabulary set **4810** of the IR controllable electrical device **4804** excludes speech patterns of all other trigger phrases. The wireless mobile device **4600** includes vocabulary sets (not shown) of other IR controllable electrical devices and controllable non-IR electrical devices, but the vocabulary set **4810** of the IR controllable electrical device **4804** is selected from among the vocabulary sets all of IR controllable electrical devices and controllable non-IR electrical devices for which the smartphone is configured to control through previous audio speech that identifies the IR controllable electrical device **4804**. Having a vocabulary set **4810** in which the speech patterns of trigger phrases that are relevant to only the IR controllable electrical device **4804** is a much smaller vocabulary set than a vocabulary set that includes speech patterns of trigger phrases that are relevant to the other controllable electrical devices. The much smaller size of the vocabulary set **4810** of the IR controllable electrical device **4804** has the effect of greatly increasing the accuracy of the speech data **4808** that is generated by the speech recognition engine **4806**, and greatly increases the speed of the speech recognition engine in the process of generating the speech data **4808**. Based on the technology of processor and bus speeds of current smartphones, this is the most superior technique to accurately and quickly provide speech data **4808** that is relevant to the IR controllable electrical device **4804** from the audio speech **4802**.

The IR controllable electrical device **4804** can be a IR controllable light, a IR controllable patient lift, a IR controllable television, a IR controllable television set-top box, a IR controllable radio, a IR controllable medication dispenser, a IR controllable bed, a IR controllable nurse call device, a IR controllable door, a IR controllable window cover, a IR controllable computer, a IR controllable medical therapeutic device, a IR controllable fan, a IR controllable, a IR controllable lamp, a IR controllable dishwasher, a IR controllable iron, a IR controllable production machinery, a IR controllable van ramp, a IR controllable cellphone or a IR controllable environmental control.

The wireless mobile device **4600** also includes a component (not shown) that is operable to convert the speech data **4808** to an ASCII string **4812**. The ASCII string **4812** identifies the IR controllable electrical device **4804** and represents control data of the IR controllable electrical device **4804** that is indicated by the audio speech **4802**.

The communication subsystem **4604** (shown in FIGS. **46** and **47**) of the wireless mobile device **4600** establishes a WIFI communication path **4814** with a WIFI wireless router **4816**. The WIFI wireless router **4816** is associated with the IR controllable electrical device **4804**. The wireless mobile

56

device **4600** is operable to transmit the ASCII string **4812** to the WIFI wireless router **4816** through the WIFI communication path **4814**.

The WIFI wireless router **4816** is operable to receive the ASCII string **4812** through the WIFI communication path **4814**. The ASCII string **4812** is stored in memory of the WIFI wireless router **4816**. The WIFI wireless router **4816** includes a component **4818** that is operable to determine that the IR controllable electrical device **4804** of the ASCII string **4812** is controlled through an infrared interface **4822**. The infrared interface **4822** through which the IR controllable electrical device **4804** is controlled is known as an associated infrared interface. The WIFI wireless router **4816** includes a component **4820** that is operable to identify a proprietary processor **4824** that is associated with the associated infrared interface **4822**. The identified proprietary processor **4824** is known as an associated proprietary processor **4824**. The WIFI wireless router **4816** is operable to transmit the ASCII string **4812** from the WIFI wireless router **4816** to the associated proprietary processor **4824**. In some implementations, the WIFI wireless router **4816** and the proprietary processor **4824** are housed in a single housing. The proprietary processor **4824** can be a processor manufactured on a mass-production line that is modified for proprietary purposes described herein, in some implementations by coupling to proprietary processor **4824** to read-only-memory that has computer-readable instructions to perform the functions described herein, or in some implementations the proprietary processor **4824** is modified after mass production to perform the functions described herein, or in some implementations the proprietary processor **4824** is modified by loading a volatile memory of the proprietary processor **4824** with computer-readable instructions to perform the functions described herein.

The proprietary processor **4824** is operable to receive from the WIFI wireless router **4816** the ASCII string **4812** and to store the ASCII string **4812** in memory. The proprietary processor **4824** includes a component (not shown) that is operable to create a socket packet **4826** from the ASCII string **4812** at the associated proprietary processor **4824**. The proprietary processor **4824** is operable to transmit the socket packet **4826** to the WIFI wireless router **4816** that is associated with the IR controllable electrical device **4804**. The transmission includes a destination address, such as an IP address, of an IP-to-IR controller **4828** that is associated with the IR controllable electrical device **4804**.

The WIFI wireless router **4816** that is associated with the IR controllable electrical device **4804** is operable to receive the socket packet **4826** and the destination address of the IR controllable electrical device **4804** from the proprietary processor **4824**.

The WIFI wireless router **4816** that is associated with the IR controllable electrical device **4804** is operable to transmit the socket packet **4826** from the WIFI wireless router **4816** that is associated with the IR controllable electrical device **4804** to the IP-to-IR controller **4828** at the destination address.

The IP-to-IR controller **4828** is operable to receive the socket packet **4826** from the WIFI wireless router **4816** that is associated with the IR controllable electrical device **4804**.

The IP-to-IR controller **4828** is operable to transmit via an infrared transmitter (not shown) an infrared signal in accordance with the socket packet **4826** to the infrared interface **4822** of the IR controllable electrical device **4804**. One example for the IR codes for particular functions of a television is shown below in Table 1:

TABLE 1

The IR controllable electrical device **4804** is operable to receive the infrared signal at the infrared interface **4822** of the IR controllable electrical device and operable to perform a function in accordance with the infrared signal, providing control of the IR controllable electrical device **4804** in accordance with the audio speech **4802**.

Routing the socket packet **4826** through the WIFI wireless router **4816** from the proprietary processor **4824** and to the IP-to-IR controller **4828** is particularly important because the IP-to-IR controller **4828** is required to be in line-of-sight to the IR controllable electrical device **4804** in order for the IR transmission between the IP-to-IR controller **4828** and the IR controllable electrical device **4804** to be effective, yet in systems where IR controllable electrical devices are located in different rooms and out of the line-of-sight, the RF communication of WIFI wireless router **4816** is necessary in order for the proprietary processor **4824** to communicate to the IR controllable electrical devices.

In some implementations, the destination IP address of the of IP-to-IR controller **4828** is encapsulated with socket packet **4826** inside a second socket packet (not shown). In some implementations, the destination IP address of the WIFI wireless router **4816** is encapsulated with the second socket packet inside a third socket packet (not shown).

An important feature of system **4800** is that the ASCII string **4812**, the socket packet **4826** and the infrared signal all represent control data of the at least one controllable electrical device that is indicated by the audio speech. **4802**. It is through this common representation by the ASCII string **4812**, the socket packet **4826** and the infrared signal of the control data of the at least one controllable electrical device that is indicated by the audio speech **4802** that the audio speech is effectively communicated across heterogeneous electrical devices, starting at the smartphone **4600** and ending at the IR controllable electrical device **4804**.

FIG. **49** is a block diagram of a system **4900** that is operable to control one or more controllable radio frequency (RF) electrical devices from audio speech, the system operable to

control the at least one RF controllable device through a wireless communication path, according to an implementation.

System **4900** includes a microphone **4620** of a wireless mobile device (smartphone) **4600** that is operable to receive audio speech **4802**. The audio speech **4802** is associated with the RF controllable electrical device **4902**. The RF controllable electrical device **4902** is an electrical device that is controllable via external radio-frequency signal(s).

The wireless mobile device **4600** also includes a speech recognition engine **4806** that is operable to generate speech data **4808** that is associated with a vocabulary set **4904** of the RF controllable electrical device **4902** from the audio speech at the wireless mobile device **4600**. The vocabulary set **4904** of the RF controllable electrical device **4902** is a set of vocabulary that includes speech patterns of trigger phrases that are relevant to the RF controllable electrical device **4902**. Speech patterns of trigger phrases that are irrelevant to the RF controllable electrical device **4902** are not included in the vocabulary set **4904** of the RF controllable electrical device **4902**. For example, when the RF controllable electrical device **4902** is a light, the vocabulary set **4904** of the RF controllable electrical device **4902** includes only trigger phrases “on”, “light on”, “off” and “light off”, and the vocabulary set **4904** of the RF controllable electrical device **4902** excludes speech patterns of all other trigger phrases. In another example, when the RF controllable electrical device **4902** is a patient lift, the vocabulary set **4904** of the RF controllable electrical device **4902** includes only trigger phrases “lower down”, “move down”, “move forward”, “forward”, “move backward”, “reverse”, “goto sleep”, “sleep”, “faster”, “slower”, “left”, “right”, “up”, “down”, “forward”, and “backward”, and the vocabulary set **4904** of the RF controllable electrical device **4902** excludes speech patterns of all other trigger phrases. The wireless mobile device **4600** includes vocabulary sets (not shown) of other RF controllable electrical devices and controllable non-RF electrical devices, but the vocabulary set **4904** of the RF controllable electrical device **4902** is selected from among the vocabulary sets all of RF controllable electrical devices and controllable non-RF electrical devices for which the smartphone is configured to control through previous audio speech that identifies the RF controllable electrical device **4902**. Having a vocabulary set **4904** in which the speech patterns of trigger phrases that are relevant to only the RF controllable electrical device **4902** is a much smaller vocabulary set than a vocabulary set that includes speech patterns of trigger phrases that are relevant to the other controllable electrical devices. The much smaller size of the vocabulary set **4904** of the RF controllable electrical device **4902** has the effect of greatly increasing the accuracy of the speech data **4808** that is generated by the speech recognition engine **4806**, and greatly increases the speed of the speech recognition engine in the process of generating the speech data **4808**. Based on the technology of processor and bus speeds of current smartphones, this is the most superior technique to accurately and quickly provide speech data **4808** that is relevant to the RF controllable electrical device **4902** from the audio speech **4802**.

The RF controllable electrical device **4902** can be a RF controllable light, a RF controllable patient lift, a RF controllable television, a RF controllable television set-top box, a RF controllable radio, a RF controllable medication dispenser, a RF controllable bed, a RF controllable nurse call device, a RF controllable door, a RF controllable window cover, a RF controllable computer, a RF controllable medical therapeutic device, a RF controllable fan, a RF controllable, a RF controllable lamp, a RF controllable dishwasher, a RF IR con-

trollableon, a RF controllable production machinery, a RF controllable van ramp, a RF controllable cellphone or a RF controllable environmental control.

The wireless mobile device **4600** also includes a component (not shown) that is operable to convert the speech data **4808** to an ASCII string **4812**. The ASCII string **4812** identifies the RF controllable electrical device **4902** and represents control data of the RF controllable electrical device **4902** that is indicated by the audio speech **4802**.

The communication subsystem **4604** (shown in FIGS. **46** and **47**) of the wireless mobile device **4600** establishes a WIFI communication path **4814** with a wireless WIFI wireless router **4906**. The WIFI wireless router **4906** is associated with the RF controllable electrical device **4902**. The wireless mobile device **4600** is operable to transmit the ASCII string **4812** to the wireless WIFI wireless router **4906** through the WIFI communication path **4814**.

The WIFI wireless router **4906** is operable to receive the ASCII string **4812** through the WIFI communication path **4814**. The ASCII string **4812** is stored in memory of the WIFI wireless router **4906**. The WIFI wireless router **4906** includes a component **4818** that is operable to determine that the RF controllable electrical device **4902** of the ASCII string **4812** is controlled through an RF receiver **4912**. The RF receiver **4912** through which the RF controllable electrical device **4902** is controlled is known as an associated RF interface. The WIFI wireless router **4906** includes a component **4820** that is operable to identify a proprietary processor **4910** that is associated with the RF electrical device **4902**. The identified proprietary processor **4910** is known as an associated proprietary processor **4910**. The WIFI wireless router **4906** is operable to transmit the ASCII string **4812** from the wireless WIFI wireless router **4906** to the associated proprietary processor **4910**. In some implementations, the wireless WIFI wireless router **4906** and the proprietary processor **4912** are housed in a single housing.

The proprietary processor **4910** is operable to receive from the WIFI wireless router **4906** the ASCII string **4812** and to store the ASCII string **4812** in memory, operable to identify the RF controllable electrical device **4902** that is controlled through an IP-to-RF controller **4908**, such as a GE Smart Remote Plus Transmitter RF102TXPS and the proprietary processor **4910** is operable to set relays of the IP-to-RF controller **4908** based on the ASCII string over a wired connection between the proprietary processor **4910** and the IP-to-RF controller **4908**.

The IP-to-RF controller **4908** is operable to transmit at least one RF control signal in accordance with the settings of the relays and the RF controllable electrical device **4902** is operable to receive an RF control signal at the RF interface **4822** and the RF controllable electrical device **4902** is operable to perform a function in accordance with the RF control signal, providing control of the RF controllable electrical device **4902** in accordance with the audio speech **4802**.

Not routing a socket packet, such as socket packet **4826** in FIG. **48**, through a WIFI wireless router from the proprietary processor **4910** and to the IP-to-RF controller **4908** is particularly important because the IP-to-RF controller **4908** is not required to be in line-of-sight to the RF controllable electrical device **4902** in order for the RF transmission between the IP-to-RF controller **4908** and the RF controllable electrical device **4902** to be effective. Yet in systems where RF controllable electrical devices **4902** are located in different rooms and out of the line-of-sight from the proprietary processor **4910**, RF communication, such as via a WIFI wireless router **4816** in FIG. **48**, is not necessary in order for the proprietary processor **4910** to communicate to the RF controllable elec-

trical devices **4902** because the IP-to-RF controller **4908** can communicate through walls to the RF controllable electrical devices **4902**; and in fact the extra step of communicating between the proprietary processor **4910** and the IP-to-RF controller **4908** through a WIFI wireless router is more complicated and error-prone.

In some implementations, the wireless WIFI wireless router **4816** and the WIFI wireless router **4906** are combined into a single WIFI wireless router and the single WIFI wireless router; the proprietary processor **4824** and the proprietary processor **4910** are combined into a single proprietary processor, the single WIFI wireless router and the single proprietary processor are housed in a single housing.

An important feature of system **4900** is that the ASCII string **4812**, relay setting of the IP-to-RF controller **4908** and the RF control signal from the IP-to-RF controller **4908** of the control data of the RF controllable electrical device **4902** that is indicated by the audio speech **4802**, that the audio speech **4802** is effectively communicated across heterogeneous electrical devices, starting at the smartphone **4600** and ending at the RF controllable electrical device **4902**.

FIG. **50** is a block diagram of a WIFI wireless router **5000**, according to an implementation. The WIFI wireless router **5000** is one example of the WIFI wireless router **4816** in FIG. **48** and the WIFI wireless router **4906** in FIG. **49**. The WIFI wireless router **5000** includes a multi-antenna signal processor **5002**, a wireless media access controller **5004** and a baseband processor **5006**, which can be incorporated as part of a single chip integrated circuit. The functions of items **4818** and **4820** in FIGS. **48** and **49** are embodied and performed by the wireless media access controller **5004**. In some implementations, can include a clock generator **5010** which generates a set of clocks for all internal modules from a 44 MHz master clock, a SDRAM buffer interface address generator in a DSP **5012** a 22 mhz three 1024-point FFT switchable circuit **5014** operable to transform received signal samples of multiple RF to the frequency domain using FFT, a 22 mhz three 1024-point IFFT switchable circuit **5016** operable to reconstruct a received signal in the time domain, a separation matrix multiplier **5018** operable to separate signals, an on chip parameter memory bank, an inter-chip data exchange interface **5020** which controls software access to internal registers as well as reading/writing of signaling messages, a digital signal processor interface, a preamble acquisition module (sync-circuit) **5022** operable to acquire timing of the received signal samples relative to a local PN code in a PLCP preamble, synchronize the signal samples to FFT frame, and use the known FFT of a preamble to estimate RF channels, four 6 bit 22 MHz A/D **5023** performs A/D conversion for I and Q baseband signals received from RF/Baseband front end circuits **5024**, and four 8 bit 44 MHz D/A **5026** operable to convert the recovered signal to an analog form and sending it out to a standard 802.11b DSSS receiver for decoding.

The DSP **5012**, which, in combination with SDRAM **5028** and D/A blocks **5026** and other elements of ASIC **5002** performs the following basic operations: Framing of the information bit stream to be transmitted; symbol mapping/encoding of the bits in a transmit frame, scrambling the transmitted data to be transmitted, modulating transmission symbols with Baker or CCK codes necessary for spreading the spectrum of the transmitted data and pre-equalizing the generated waveforms in a frequency domain.

61

FIG. 51-56 are diagrams 5100-5600 of handheld mobile device graphical user interfaces selected to control electrical devices, according to implementations. The operator of the handheld mobile device can navigate to one of the diagrams 5100-5600, and then a vocabulary set or a linguist component 1616 that is limited to the operations and operands of the electrical device(s) represented in the displayed graphical user interface is referenced during speech recognition of the audio speech to the exclusion of vocabulary sets or a linguist components 1616 that are not associated with the electrical device(s) represented in the displayed graphical user interface. This is an important feature because the selected vocabulary set is specifically limited to the selected controllable electrical device(s). The selected vocabulary set includes data that is relevant only to the selected controllable electrical device, which is greatly helpful in providing faster processing of the audio speech 4802 but also is greatly helpful in providing more accurate processing of the audio speech 4802.

FIG. 51 is a diagram 5100 of a handheld mobile device graphical user interface selected to control a patient bed electrical device.

FIG. 52 is a diagram 5200 of a handheld mobile device graphical user interface selected to control a digital video recorder electrical device that is located in a bedroom.

FIG. 53 is a diagram 5300 of a handheld mobile device graphical user interface selected to control an electrical devices located in a first bedroom.

FIG. 54 is a diagram 5400 of a handheld mobile device graphical user interface selected to control a security camera electrical device located at a front door.

FIG. 55 is a diagram 5500 of a handheld mobile device graphical user interface selected to control a digital video recorder electrical device.

FIG. 56 is a diagram 5600 of a handheld mobile device graphical user interface selected to control a patient bed electrical device.

In some implementations, display screens and command sets are associated in global, local and by room. Global commands can be executed from any location and any room. For example, when the operator selects "Location 1" (either via audio speech 4802 or by selecting "location 1" from a display), the screen of the smartphone will change to display "Location 1" electrical devices and vocabulary set of the electrical device of "location 1" will also be loaded into memory of the smartphone and the vocabulary set for electrical devices that are not associated with "location 1" will be deallocated from memory. In another example, when the operator selects "Make Phone Call" (either via audio speech 4802 or by selecting "phone" from a display), the screen of the smartphone will change to display "phone" functions and vocabulary set of the phone functions will also be loaded into memory of the smartphone and the vocabulary set for electrical devices that are not associated with the phone functions will be deallocated from memory of the smartphone. In another example, when the operator selects "call 911" (either via audio speech 4802 or by selecting "911" from a display), the screen of the smartphone will change to display emergency call functions and vocabulary set of the emergency call functions will also be loaded into memory of the smartphone and the vocabulary set for functions that are not associated with emergency call functions will be deallocated from memory of the smartphone.

Local commands can be from any room in close proximity to the smartphone.

For example, when the operator selects "room 1" (either via audio speech 4802 or by selecting "room 1" from a display),

62

the screen of the smartphone will change to display "room 1" electrical devices of that location and vocabulary set of the electrical device of "room 1" will also be loaded into memory of the smartphone and the vocabulary set for electrical devices that are not associated with "room 1" will be deallocated from memory. The smartphone can be configured to control more than one "Room 1" but each of the "room 1"'s must be in separate locations.

For example, when the operator selects "Open the Front Door" (either via audio speech 4802 or by selecting "Open the Front Door" from a display), the screen of the smartphone will change to display "Front Door" of the building and vocabulary set of the electrical device of "the Front Door" will also be loaded into memory of the smartphone and the vocabulary set for electrical devices that are not associated with "the Front Door" will be deallocated from memory and the front door of the building will be opened from any room in the building.

For example, when the operator selects "Room 3 light on" (either via audio speech 4802 or by selecting "Room 3 light on" from a display), the screen of the smartphone will change to display "Room 3" electrical devices and vocabulary set of the electrical device of "Room 3 light" will also be loaded into memory of the smartphone and the vocabulary set for electrical devices that are not associated with "Room 3 light on" will be deallocated from memory and the light of room 3 of the building will be turned on from any room in the building.

The smartphone can be configured to add room commands to the local commands so that functions of electrical devices in any room can be controlled.

Room commands are executable only when that Room Screen is selected by the operator. Room commands are specific to a particular screen so that different electrical devices can be controlled with similar commands. An example would be a two TVs in deferent rooms, each should respond individually to commands like "Turn On" and "Channel Up".

In some implementations, multisensory input is performed from either or both the audio speech 4802 and tactile sensing of selections performed through contact with the touchpad display screen from an external object such as a finger. In that case, control of the electrical devices can be made by the operator through audio speech 4802 and/or by selection via a touchpad display screen on the handheld mobile device.

Computer storage media include volatile and nonvolatile, removable and non-removable media, implemented in any method or technology for storage of information, such as computer-readable instructions, data structures, program modules or other data. The term "computer storage media" includes, but is not limited to, RAM, ROM, EEPROM, FLASH memory or other memory technology, CD, DVD, or other optical storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic non-transitory storage devices, or any other media which can be used to store computer-intelligible information and which can be accessed by the computation resource 4702.

Communication media typically implements computer-readable instructions, data structures, program modules or other data; and includes any information delivery media.

By way of example, and not limitation, communication media include wired media, such as wired network or direct-wired connections, and wireless media, such as acoustic, RF, infrared and other wireless media. The scope of the term computer-readable media includes combinations of any of the above.

Apparatus components of FIG. 1-16 can be implemented as computer hardware circuitry or as a computer-readable program, or a combination of both. In another implementa-

tion, system in FIG. 1 and FIG. 2 are implemented in an application service provider (ASP) system.

The terminology used herein is for the purpose of describing particular implementations only and is not intended to limit the inventions. As used herein, the singular forms “a”, “an” and “the” are intended to include the plural forms as well, unless the context clearly indicates otherwise. The terms “comprises” and/or “comprising,” when used in this specification, specify the presence of stated features, integers, steps, operations, elements, and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components, and/or groups thereof.

The corresponding structures, materials, acts, and equivalents of all means or step plus function elements in the claims below are intended to include any structure, material, or act for performing the function in combination with other claimed elements as specifically claimed. The description has been presented for purposes of illustration and description, but is not intended to be exhaustive or limited in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art without departing from the scope and spirit of the inventions. Implementations are chosen and described in order to best explain the principles and the practical application, and to enable others of ordinary skill in the art to understand various implementations with various modifications as are suited to the particular use contemplated.

In the above detailed description, reference is made to the accompanying drawings that form a part hereof, and in which is shown by way of illustration specific implementations which may be practiced. These implementations are described in sufficient detail to enable those skilled in the art to practice the implementations, and other implementations may be utilized and that logical, mechanical, electrical and other changes may be made without departing from the scope of the implementations. The following detailed description is, therefore, not to be taken in a limiting sense.

As will be appreciated by one skilled in the art, the present inventions may be implemented as a system, method or computer program product. Accordingly, the present inventions may take the form of an entirely hardware implementation, an entirely software implementation (including firmware, resident software, micro-code, etc.) or an implementation combining software and hardware aspects that may all generally be referred to herein as a “circuit,” “module” or “system.” Furthermore, the present inventions may take the form of a computer program product implemented in any tangible medium of expression having computer-usable program code implemented in the medium.

Any combination of one or more computer usable or computer readable medium(s) may be utilized. The computer-usable or computer-readable medium may be, for example but not limited to, an electronic, magnetic, optical, electro-magnetic, infrared, or semiconductor system, apparatus, device, or propagation medium. More specific examples (a non-exhaustive list) of the computer-readable medium do include the following: an electrical connection having one or more wires, a portable computer diskette, a hard disk, a random access memory (RAM), a read-only memory (ROM), an erasable programmable read-only memory (EPROM or Flash memory), an optical fiber, a portable compact disc read-only memory (CD-ROM), an optical non-transitory storage device, a transmission media such as those supporting the Internet or an intranet, or a magnetic non-transitory storage device. In the context of this document, a computer-usable or computer-readable medium may be any medium that can

contain, store, communicate, propagate, or transport the program for use by or in connection with the instruction execution system, apparatus, or device. The computer usable program code may be transmitted using any appropriate medium, including but not limited to wireless, wireline, optical fiber cable, RF, etc.

In computer-readable program implementations, the programs can be structured in an object-orientation using an object-oriented language such as Java, Smalltalk or C++, and the programs can be structured in a procedural-orientation using a procedural language such as COBOL or C. The software components communicate in any of a number of means that are well-known to those skilled in the art, such as application program interfaces (API) or interprocess communication techniques such as remote procedure call (RPC), common object request broker architecture (CORBA), Component Object Model (COM), Distributed Component Object Model (DCOM), Distributed System Object Model (DSOM) and Remote Method Invocation (RMI). The components execute on as few as one computer as in computer environment 4700 in FIG. 47, or on at least as many computers as there are components.

Computer program code for carrying out operations of the present inventions may be written in any combination of one or more programming languages, including an object oriented programming language such as Java, Smalltalk, C++ or the like and conventional procedural programming languages, such as the “C” programming language or similar programming languages. The program code may execute entirely on the user’s computer, partly on the user’s computer, as a stand-alone software package, partly on the user’s computer and partly on a remote computer or entirely on the remote computer or server. In the latter scenario, the remote computer may be connected to the user’s computer through any type of network, including a local area network (LAN) or a wide area network (WAN), or the connection may be made to an external computer (for example, through the Internet using an Internet Service Provider).

The present inventions are described above with reference to flowchart illustrations and/or block diagrams of methods, apparatus (systems) and computer program electrical device (s) 114 according to implementations. Each block of the flowchart illustrations and/or block diagrams, and combinations of blocks in the flowchart illustrations and/or block diagrams, can be implemented by computer program instructions. These computer program instructions may be provided to a processor of a general purpose computer, special purpose computer, or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer or other programmable data processing apparatus, create means for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

These computer program instructions may also be stored in a computer-readable medium that can direct a computer or other programmable data processing apparatus to function in a particular manner, such that the instructions stored in the computer-readable medium produce an article of manufacture including instruction means which implement the function/act specified in the flowchart and/or block diagram block or blocks.

The computer program instructions may also be loaded onto a computer or other programmable data processing apparatus to cause a series of operational steps to be performed on the computer or other programmable apparatus to produce a computer implemented process such that the instructions which execute on the computer or other program-

65

mable apparatus provide processes for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

Some implementations include a computer program product that includes a computer-usable medium having computer-usable program code implemented therewith, the computer-usable program code including computer-usable program code configured to perform specific functions. Some implementations include a field-programmable gate array that is operable to perform specific functions. Some implementations include a computer-accessible medium having executable instructions capable of directing a processor to perform specific functions. Some implementations include a computer-usable medium including a program to control a patient-lifting-device, the program comprising computer program code to perform specific functions. Some method implementations include representing a specific original physical reality with specific original data, electronically transforming the specific original data into specific transformed data using a novel and non-obvious process, and representing the specific transformed data as a specific transformed physical reality in the form of a visual depiction.

CONCLUSION

An omni-input electrical device command system is described. A technical effect of the system is electrical control of one or more electrical devices in reference to commands received from voice input from a hand-held mobile device. Although specific implementations are illustrated and described herein, it will be appreciated by those of ordinary skill in the art that any arrangement which is calculated to achieve the same purpose may be substituted for the specific implementations shown. This application is intended to cover any adaptations or variations. One of ordinary skill in the art will appreciate that implementations can be made in software implementation or any other hardware implementation that provides the required function.

In particular, one of skill in the art will readily appreciate that the names of the methods and apparatus are not intended to limit implementations. Furthermore, additional methods and apparatus can be added to the components, functions can be rearranged among the components, and new components to correspond to future enhancements and physical devices used in implementations can be introduced without departing from the scope of implementations. One of skill in the art will readily recognize that implementations are applicable to future patient-lifting-devices and different command input devices.

The terminology used in this application meant to include all patient-lifting-devices, and voice recognition systems and alternate technologies which provide the same functionality as described herein.

The invention claimed is:

1. A system that is operable to control at least one IR controllable electrical device from audio speech, the system operable to control the at least one IR controllable electrical device through a wireless communication path, and the system being operable to:

receive the audio speech that is associated with the at least one IR controllable electrical device at a microphone of a wireless mobile device;
generate speech data that is associated with a vocabulary set of the at least one IR controllable electrical device from the audio speech at the wireless mobile device;
convert the speech data to an ASCII string that is associated with the at least one IR controllable electrical device at

66

the wireless mobile device, the ASCII string representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
establish a WIFI communication path with a WIFI wireless router that is associated with the at least one IR controllable electrical device at the wireless mobile device;
send the ASCII string from the wireless mobile device to the WIFI wireless router that is associated with the at least one IR controllable electrical device through the WIFI communication path, the ASCII string representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
receive the ASCII string at the WIFI wireless router through the WIFI communication path, the ASCII string representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
determine that at the least one IR controllable electrical device of the ASCII string is controlled through an infrared interface, yielding an associated infrared interface, the ASCII string representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
determine a proprietary processor that is associated with the associated infrared interface, yielding an associated proprietary processor;
send the ASCII string from the WIFI wireless router to the associated proprietary processor, the ASCII string representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
receive from the router the ASCII string at the associated proprietary processor;
create a socket packet from the ASCII string at the associated proprietary processor, the socket packet representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
send the socket packet from the associated proprietary processor to the WIFI wireless router that is associated with the at least one IR controllable electrical device, the sending having a destination address of an IP-to-IR controller;
receive the socket packet at the WIFI wireless router that is associated with the at least one IR controllable electrical device from the proprietary processor, the socket packet representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
send the socket packet from the WIFI wireless router that is associated with the at least one IR controllable electrical device to the IP-to-IR controller;
receive the socket packet at the IP-to-IR controller and from the WIFI wireless router that is associated with the at least one IR controllable electrical device, the socket packet representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
send an infrared signal in accordance with the socket packet from the IP-to-IR controller to the infrared interface of the at least one IR controllable electrical device, the infrared signal representing control data of the at least one IR controllable electrical device that is indicated by the audio speech;
receive the infrared signal from the IP-to-IR controller at the infrared interface of the at least one IR controllable electrical device, the infrared signal representing control data of the at least one IR controllable electrical device that is indicated by the audio speech; and

67

perform a function in accordance with the infrared signal at the at least one IR controllable electrical device, providing control of the at least one IR controllable electrical device in accordance with the audio speech.

2. The system of claim 1, further comprising a second socket packet, the second socket packet comprising:

the socket packet; and
the destination IP address of the IP-to-IR controller.

3. The system of claim 2, further comprising a third socket packet, the third socket packet comprising:

the second socket packet; and
a destination IP address of the WIFI wireless router.

4. The system of claim 1, wherein the at least one IR controllable electrical device further comprises:

an IR controllable door.

5. The system of claim 1, wherein the at least one IR controllable electrical device further comprises:

an IR controllable television.

6. The system of claim 1, wherein the at least one IR controllable electrical device further comprises:

an IR controllable DVD player.

7. A method performed by a wireless mobile device to control at least one controllable electrical device from audio speech, the method comprising:

receiving the audio speech that is associated with the at least one controllable electrical device at a microphone of the wireless mobile device;

generating speech data that is associated with a vocabulary set of the at least one controllable electrical device from the audio speech;

converting the speech data to an ASCII string that is associated with the at least one controllable electrical device at the wireless mobile device, the ASCII string representing control data of the at least one controllable electrical device that is indicated by the audio speech;

establishing a WIFI communication path with a WIFI wireless router that is associated with the at least one controllable electrical device at the wireless mobile device; and

sending the ASCII string from the wireless mobile device to the WIFI wireless router that is associated with the at least one controllable electrical device through the WIFI communication path.

8. The method of claim 7, wherein the at least one controllable electrical device further comprises:

a controllable door.

9. The method of claim 7, wherein the at least one controllable electrical device further comprises:

a controllable television.

10. The method of claim 7, wherein the at least one controllable electrical device further comprises:

a controllable DVD player.

11. An apparatus that is operable to control at least one IR controllable electrical device from audio speech, the system

68

operable to control the at least one IR controllable electrical device through a wireless communication path, the apparatus comprising:

a WIFI wireless router comprising a baseband processor and a wireless controller:

the baseband processor being operable to:

establish a WIFI wireless communication path with a wireless mobile device;

receive through the WIFI wireless communication path an ASCII string that represents speech data that is associated with a vocabulary set of the at least one IR controllable electrical device; and

the wireless controller being coupled to the baseband processor and being operable to:

determine that at the least one IR controllable electrical device of the ASCII string is controlled through an infrared interface, yielding an associated infrared interface;

determine a proprietary processor that is associated with the associated infrared interface, yielding an associated proprietary processor; and

send the ASCII string from the wireless WIFI wireless router to the associated proprietary processor; and

the associated proprietary processor coupled to the WIFI wireless router, the associated proprietary processor operable to:

receive the ASCII string from the WIFI wireless router; create a socket packet from the ASCII string;

send the socket packet the WIFI wireless router, the sending having a destination address of an IP-to-IR controller; and

the WIFI wireless router further comprising:

the wireless controller further operable to:

receive the socket packet from the proprietary processor; and

send the socket packet from the wireless WIFI wireless router to the IP-to-IR controller.

12. The apparatus of claim 11, further comprising a second socket packet, the second socket packet comprising:

the socket packet; and

the destination IP address of the IP-to-IR controller.

13. The apparatus of claim 12, further comprising a third socket packet, the third socket packet comprising:

the second socket packet; and

a destination IP address of the WIFI wireless router.

14. The apparatus of claim 11, wherein the at least one IR controllable electrical device further comprises:

an IR controllable door.

15. The apparatus of claim 11, wherein the at least one IR controllable electrical device further comprises:

an IR controllable television.

16. The apparatus of claim 11, wherein the at least one IR controllable electrical device further comprises:

an IR controllable DVD player.
